Semantic conventions and instrumentation is treated here as an engineering capability rather than a vocabulary item. Define stable names, units, attributes, status, errors, and domain conventions across services and agents. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for semantic conventions and instrumentation.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Implementation sketch

```
from __future__ import annotations

import asyncio
from dataclasses import dataclass

@dataclass(frozen=True, slots=True)
class WorkItem:
    name: str

async def execute_semantic_conventions_and_instrumentation(item: WorkItem) -> None:
    async with asyncio.timeout(30):
        # Validate, instrument, and make side effects explicit.
        await asyncio.sleep(0)
```

Failure patterns

- Treating semantic conventions and instrumentation as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for semantic conventions and instrumentation.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

5.3 Collection, sampling, routing, and storage

Collection, sampling, routing, and storage is treated here as an engineering capability rather than a vocabulary item. Engineer agents, collectors, pipelines, tail sampling, filtering, transformation, retention, and cost. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for collection, sampling, routing, and storage.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating collection, sampling, routing, and storage as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for collection, sampling, routing, and storage.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

5.4 Dashboards, alerts, and investigative workflows

Dashboards, alerts, and investigative workflows is treated here as an engineering capability rather than a vocabulary item. Design views around decisions, hypotheses, service objectives, and incident questions rather than metric accumulation. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency,

orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for dashboards, alerts, and investigative workflows.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating dashboards, alerts, and investigative workflows as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for dashboards, alerts, and investigative workflows.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

Chapter 05 laboratory and review

Practical laboratory
Instrument an application and data pipeline end to end, then diagnose latency using correlated traces, queries, logs, system metrics, and storage telemetry.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Evaluate eBPF, continuous profiling, AI-assisted investigation, and privacy-preserving telemetry.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

SRE, service objectives, and reliability economics

Manage reliability as an explicit product property with measurable risk, capacity, and operational tradeoffs.

Chapter operating position

Manage reliability as an explicit product property with measurable risk, capacity, and operational tradeoffs.

6.1 SLIs, SLOs, and error budgets

SLIs, SLOs, and error budgets is treated here as an engineering capability rather than a vocabulary item. Measure user-relevant success, latency, freshness, durability, and availability and define acceptable unreliability. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for slis, slos, and error budgets.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating slis, slos, and error budgets as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for slis, slos, and error budgets.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

6.2 Capacity, performance, and saturation

Capacity, performance, and saturation is treated here as an engineering capability rather than a vocabulary item. Model demand, limits, queues, storage growth, hot keys, compaction, and scaling behavior. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for capacity, performance, and saturation.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Implementation sketch

```
from __future__ import annotations

import asyncio
from dataclasses import dataclass

@dataclass(frozen=True, slots=True)
class WorkItem:
    name: str

async def execute_capacity_performance_and_saturation(item: WorkItem) -> None:
    async with asyncio.timeout(30):
        # Validate, instrument, and make side effects explicit.
        await asyncio.sleep(0)
```

Failure patterns

- Treating capacity, performance, and saturation as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for capacity, performance, and saturation.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

6.3 Toil, automation, and operational load

Toil, automation, and operational load is treated here as an engineering capability rather than a vocabulary item. Identify repetitive human work, automate proven procedures, and track cognitive and support burden. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for toil, automation, and operational load.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating toil, automation, and operational load as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for toil, automation, and operational load.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

6.4 Incidents, postmortems, and learning systems

Incidents, postmortems, and learning systems is treated here as an engineering capability rather than a vocabulary item. Coordinate response, preserve timelines and evidence, analyze contributing conditions, and improve controls. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency,

orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for incidents, postmortems, and learning systems.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating incidents, postmortems, and learning systems as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for incidents, postmortems, and learning systems.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

Chapter 06 laboratory and review

Practical laboratory

Define SLOs for a data API, overload it, exhaust storage, and inject replica lag. Use error budgets and capacity evidence to prioritize remediation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore carbon-aware reliability, autonomous operations, and economic control loops that account for risk and energy.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Evidence, provenance, integrity, and assurance

Preserve trustworthy records of what data existed, how it changed, who acted, and what was verified.

Chapter operating position
Preserve trustworthy records of what data existed, how it changed, who acted, and what was verified.

7.1 Hash chains, signatures, and tamper evidence

Hash chains, signatures, and tamper evidence is treated here as an engineering capability rather than a vocabulary item. Use digests, signatures, transparency, sequence, and checkpoints to detect unauthorized modification. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for hash chains, signatures, and tamper evidence.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating hash chains, signatures, and tamper evidence as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for hash chains, signatures, and tamper evidence.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

7.2 Data and model provenance

Data and model provenance is treated here as an engineering capability rather than a vocabulary item. Track origin, licenses, transformations, code, environment, versions, owners, and derived artifacts. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for data and model provenance.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Implementation sketch

```
from __future__ import annotations

import asyncio
from dataclasses import dataclass

@dataclass(frozen=True, slots=True)
class WorkItem:
    name: str

async def execute_data_and_model_provenance(item: WorkItem) -> None:
    async with asyncio.timeout(30):
        # Validate, instrument, and make side effects explicit.
        await asyncio.sleep(0)
```

Failure patterns

- Treating data and model provenance as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for data and model provenance.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

7.3 Audit trails and chain of custody

Audit trails and chain of custody is treated here as an engineering capability rather than a vocabulary item. Preserve identity, time, action, source, handling, access, and transfer records for investigations and assurance. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for audit trails and chain of custody.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating audit trails and chain of custody as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for audit trails and chain of custody.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

7.4 Evidence bundles and verification

Evidence bundles and verification is treated here as an engineering capability rather than a vocabulary item. Package claims, inputs, outputs, logs, tests, approvals, hashes, and limitations into independently reviewable artifacts. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

Define the authoritative source and ownership boundary for evidence bundles and verification.

Make preconditions, invariants, error states, and recovery actions explicit.

Instrument the critical path with stable identifiers, timestamps, and outcome codes.

Validate in a representative environment before widening blast radius.

Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

Treating evidence bundles and verification as a product feature rather than an end-to-end engineering behavior.

Automating an undocumented process and scaling its ambiguity.

Relying on a happy-path demonstration without degraded-state or rollback testing.

Using aggregate dashboards without retaining trace-level evidence.

Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for evidence bundles and verification.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

Chapter 07 laboratory and review

Practical laboratory
Create a signed evidence bundle for a data migration, including source inventory, transforms, row counts, checksums, exceptions, approvals, and rollback.

Laboratory evidence package

Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.

Versioned configuration or code with explanatory comments and reproducible setup instructions.

Nominal-path validation plus at least two injected failure or boundary conditions.

Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.

A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Evaluate verifiable databases, zero-knowledge proofs, confidential analytics, and decentralized transparency systems.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Privacy, sovereignty, local-first data, and frontier systems

Engineer data locality, user ownership, controlled synchronization, privacy, and emerging storage architectures.

Chapter operating position
Engineer data locality, user ownership, controlled synchronization, privacy, and emerging storage architectures.

8.1 Classification, minimization, and purpose limitation

Classification, minimization, and purpose limitation is treated here as an engineering capability rather than a vocabulary item. Collect only needed data, label sensitivity, restrict use, define retention, and enforce lifecycle deletion. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for classification, minimization, and purpose limitation.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating classification, minimization, and purpose limitation as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for classification, minimization, and purpose limitation.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

8.2 Residency, sovereignty, and egress control

Residency, sovereignty, and egress control is treated here as an engineering capability rather than a vocabulary item. Track jurisdiction, storage, processing, operator access, keys, telemetry, transfer, and external dependencies. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for residency, sovereignty, and egress control.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Implementation sketch

```python
from __future__ import annotations

import asyncio
from dataclasses import dataclass

@dataclass(frozen=True, slots=True)
class WorkItem:
    name: str

async def execute_residency_sovereignty_and_egress_control(item: WorkItem) -> None:
    async with asyncio.timeout(30):
        # Validate, instrument, and make side effects explicit.
        await asyncio.sleep(0)
```

Failure patterns

- Treating residency, sovereignty, and egress control as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for residency, sovereignty, and egress control.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

8.3 Local-first synchronization and conflict resolution

Local-first synchronization and conflict resolution is treated here as an engineering capability rather than a vocabulary item. Support offline work, replicas, merges, collaboration, identity, encryption, and safe reconnection. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency, orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for local-first synchronization and conflict resolution.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating local-first synchronization and conflict resolution as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for local-first synchronization and conflict resolution.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

8.4 Frontier data architectures

Frontier data architectures is treated here as an engineering capability rather than a vocabulary item. Assess computational storage, vector-native data, knowledge graphs, synthetic data, and autonomous data management. The design objective is to make the behavior understandable before it is automated, measurable before it is optimized, and recoverable before it is scaled.

Within MYTHOS-DAT - Data, State, Storage, Reliability & Observability, this capability should be represented through explicit boundaries, typed or otherwise enforceable contracts, observable state transitions, and named owners. A production design separates intent from mechanism, control-plane decisions from data-plane execution, and nominal behavior from degraded or adversarial behavior. The resulting system is easier to test, review, migrate, and operate because its assumptions are visible rather than embedded in tribal knowledge.

Implementation begins with a small, inspectable baseline. Establish the authoritative inputs, expected outputs, invariants, timeout and retry behavior, identity context, telemetry, and rollback path. Only then add abstraction, concurrency,

orchestration, optimization, or autonomous behavior. This sequence prevents sophistication from hiding incomplete fundamentals and makes later evidence comparable across revisions.

Engineering practices

- Define the authoritative source and ownership boundary for frontier data architectures.
- Make preconditions, invariants, error states, and recovery actions explicit.
- Instrument the critical path with stable identifiers, timestamps, and outcome codes.
- Validate in a representative environment before widening blast radius.
- Capture repeatable evidence so another engineer can reproduce the conclusion.

Failure patterns

- Treating frontier data architectures as a product feature rather than an end-to-end engineering behavior.
- Automating an undocumented process and scaling its ambiguity.
- Relying on a happy-path demonstration without degraded-state or rollback testing.
- Using aggregate dashboards without retaining trace-level evidence.
- Allowing ownership, version, or authority to become implicit.

Validation and evidence

Method	Expected evidence
Examine	Architecture, configuration, contracts, runbooks, and source authority for frontier data architectures.
Interview	Engineers and operators responsible for design, implementation, review, and incident ownership.
Test	Nominal, boundary, failure, timeout, recovery, and rollback scenarios with retained evidence.
Measure	Correctness, latency, reliability, resource use, security outcomes, and operator effort.

Chapter 08 laboratory and review

Practical laboratory

Build a local-first dataset that supports offline edits from two replicas and demonstrates conflict detection, merge policy, encrypted sync, and audit history.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Define readiness gates for confidential data collaboration, federated learning, and sovereign AI data planes.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. PostgreSQL Global Development Group - PostgreSQL Documentation
Role: Relational data, transactions, replication, indexing, backup, and operations reference.
Verified: 2026-07-26
Official source: https://www.postgresql.org/docs/

02. SQLite Project - SQLite Documentation
Role: Embedded and local data architecture reference.
Verified: 2026-07-26
Official source: https://www.sqlite.org/docs.html

03. OpenTelemetry - OpenTelemetry Semantic Conventions
Role: Vendor-neutral telemetry semantics for distributed, cloud-native, and AI systems.
Verified: 2026-07-26
Official source: https://opentelemetry.io/docs/specs/semconv/

04. Google - Site Reliability Engineering Books
Role: Service reliability, SLO, error-budget, incident, and capacity practices.
Verified: 2026-07-26
Official source: https://sre.google/books/

05. NIST NCCoE - Data Integrity: Recovering from Ransomware and Other Destructive Events
Role: Data integrity, backup, restoration, and recovery assurance guidance.
Verified: 2026-07-26
Official source: https://www.nccoe.nist.gov/projects/data-integrity

06. SLSA Project - Supply-chain Levels for Software Artifacts Specification
Role: Software supply-chain integrity, provenance, build, source, and verification requirements.
Verified: 2026-07-26
Official source: https://slsa.dev/spec/

07. Cloud Native Computing Foundation - CloudEvents Specification
Role: Portable event metadata and interoperability model.
Verified: 2026-07-26
Official source: https://cloudevents.io/

08. NIST - Confidential Computing and Trusted Platforms Publications
Role: Trusted computing, attestation, roots of trust, and platform integrity reference.
Verified: 2026-07-26
Official source: https://csrc.nist.gov/topics/technologies/trusted-computing

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Living Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Contents

Executive operating doctrine

Knowledge, data, identity, and learning form the durable substrate around AI. Grounded decisions require authoritative sources, controlled state, explicit identity, verifiable evidence, user-governed memory, and measurable human capability.

Standards map

ID	PUBLICATION	CRITERIA
MYTHOS-KNW-0001	RAG, Grounding & Source Authority Standard Defines retrieval-augmented generation, grounding, citation, source authority, freshness, conflict handling, provenance, and evidence requirements for knowledge-backed AI systems.	12
MYTHOS-KNW-0002	Persona, Avatar & Persistent Memory Architecture Standard Establishes architecture and governance for persistent persona, embodied presence, user-controlled memory, continuity, provenance, privacy, and lifecycle management.	12
MYTHOS-DAT-0001	Vector Database & Local-First Sync Architecture Standard Defines vector retrieval and local-first synchronization architecture, including indexing, embeddings, consistency, conflict resolution, offline operation, provenance, and lifecycle control.	12
MYTHOS-DAT-0002	AI & Agent Observability Semantic Conventions (OpenTelemetry) Standard Establishes semantic conventions and operational requirements for observing models, agents, tools, retrieval, memory, costs, safety events, and end-to-end AI execution traces.	11
MYTHOS-DAT-0003	Data Sovereignty, Privacy Preservation, & Egress Control Standard Defines data sovereignty, privacy preservation, residency, classification, egress control, minimization, policy enforcement, and accountable cross-boundary processing.	14
MYTHOS-DAT-0004	Event Sourcing, CQRS, & Durable State Machine Standard Establishes event-sourcing, CQRS, durable state-machine, replay, idempotency, consistency, migration, and evidence requirements for authoritative state systems.	12
MYTHOS-DAT-0005	Tamper-Evident Hash-Chained Ledgers & Evidence Bundle Standard Defines tamper-evident ledgers and evidence bundles for consequential system actions, including hash chaining, signatures, provenance, retention, verification, and disclosure boundaries.	12
MYTHOS-ID-0001	Workload, Agent & Human Identity Standard Defines identity architecture for humans, workloads, services, agents, tools, and devices with attestation, federation, lifecycle, delegation, authentication, and audit requirements.	12
MYTHOS-ID-0002	Public Key Infrastructure (PKI) & Attribute-Based Access Control (ABAC) Standard Establishes public-key infrastructure and attribute-based access-control requirements for trust anchors, certificate lifecycle, policy decision, authorization context, revocation, and evidence.	12
MYTHOS-EDU-0001	Adaptive Learning, Skill Graphs & Cyber Lab Standard Defines adaptive learning, skill graphs, competency evidence, cyber labs, assessment, accessibility, credential portability, safety, and workforce-assurance requirements.	12

Connected governance chain

SYSTEM	AUTHORITATIVE QUESTION	CONTROL REQUIREMENT
Knowledge	What sources support the decision, how authoritative are they, and how fresh are they?	Preserve citations, source snapshots, conflicts, access decisions, and uncertainty.
Data and state	What is the authoritative state, who may change it, and how is it recovered?	Use typed state models, durable events, integrity, replay, retention, and reconciliation.
Identity	Which human, workload, service, agent, device, or tool is acting?	Authenticate and attest the principal; bind lifecycle, delegation, and revocation.
Authorization	What may this principal do to this resource in this context?	Evaluate policy externally and issue narrow, expiring, observable capability.
Evidence	How can the decision and resulting state be independently reconstructed?	Retain tamper-evident provenance, approvals, verification, and final disposition.
Learning	What capability changed, how was it measured, and what evidence supports the credential?	Use transparent skill models, authentic assessment, accessibility, and revocable credentials.

Knowledge authority and grounding

SOURCE CLASS	TYPICAL AUTHORITY	REQUIRED TREATMENT
Normative authority	Law, regulation, contract, approved policy, or controlled standard.	Pin exact version, jurisdiction, applicability, owner, and expiration.
Primary technical source	Official specification, standard, protocol registry, or product documentation.	Record version and retrieval date; distinguish specification from observed behavior.
Operational evidence	Logs, tests, measurements, tickets, state snapshots, and signed records.	Protect integrity, time, identity, collection method, retention, and access.
Qualified analysis	Reviewed research, expert assessment, or approved internal analysis.	Record method, assumptions, conflicts, confidence, and review date.
Secondary synthesis	Books, articles, summaries, and explanatory material.	Use for context, not as sole support for consequential claims.
Untrusted or user-generated	Forums, model output, anonymous material, and uncontrolled uploads.	Isolate, label, validate, and prohibit silent promotion into authoritative memory.

Data, state, and evidence architecture

STATE CONCERN	DESIGN QUESTION	ASSURANCE MECHANISM
Authority	Which store or event stream is authoritative for each entity and decision?	Explicit source-of-truth ownership and conflict policy.
Consistency	What stale, divergent, or partial states are acceptable?	Declared consistency model, version vectors, idempotency, and reconciliation.
Durability	What must survive process, host, region, and dependency failure?	Write-ahead or event records, checkpoints, backup, restore, and recovery testing.
Privacy and sovereignty	Where may data be stored, processed, embedded, retrieved, or disclosed?	Classification, residency, minimization, egress control, deletion, and legal basis.
Integrity	How are unauthorized change and evidence tampering detected?	Signatures, hashes, append-only records, access control, and verification.
Lifecycle	When is state corrected, migrated, archived, expired, or destroyed?	Versioned schemas, retention schedules, tombstones, and auditable deletion.
Observability	Can operators explain state transitions and diagnose divergence?	Correlated traces, events, metrics, logs, and state snapshots.

Identity, delegation, and authorization

PRINCIPAL	IDENTITY PROOF	AUTHORIZATION POSTURE
Human	Phishing-resistant authentication, account lifecycle, device and session context.	Role, attribute, risk, purpose, and step-up controls with accountable approval.
Workload or service	Workload identity, platform attestation, signed deployment, and runtime context.	Short-lived service capability bound to environment, audience, and resource.
Agent	Authenticated runtime instance, mission identity, model and configuration lineage.	Delegated capability restricted by mission, tool, target, budget, and expiration.
Tool or extension	Signed publisher identity, package provenance, version, permissions, and trust tier.	Explicit grants, sandbox tier, network and filesystem restrictions, and revocation.
Device	Hardware or software identity, posture, ownership, and attestation.	Conditional access based on compliance, location, risk, and intended function.
Data subject or persona	Verified account relationship, consent, preferences, and representation constraints.	Purpose limitation, user control, privacy, correction, deletion, and impersonation resistance.

Adaptive learning and workforce assurance

LEARNING ELEMENT	CONTROLLED IMPLEMENTATION	EVIDENCE
Skill graph	Versioned competencies, prerequisites, proficiency levels, and role mappings.	Approved ontology and change history.
Adaptive path	Recommendations based on demonstrated gaps, goals, accessibility, and pace.	Explainable recommendation and learner control.
Cyber lab	Isolated, resettable, observable environment with scenario and safety boundaries.	Lab configuration, activity telemetry, and cleanup evidence.
Assessment	Authentic task, rubric, anti-cheating controls, and human escalation.	Scored artifact, evaluator identity, method, and confidence.
Credential	Portable, verifiable achievement tied to evidence and issuer.	Signed credential, criteria, evidence reference, issue and expiration.
Continuous assurance	Revalidation after time, role, technology, or risk change.	Review schedule, reassessment result, remediation, and revocation state.

Cross-domain failure and recovery

FAILURE	IMPACT	CONTROL RESPONSE
Source-authority inversion	Low-quality or adversarial content becomes trusted knowledge.	Quarantine, compare authority, restore lineage, and invalidate derived memory.
Stale grounding	Decision cites an obsolete specification, policy, identity, or state snapshot.	Enforce freshness windows, expiration, revalidation, and conflict display.
Identity confusion	Agent, service, person, or device is misattributed.	Deny action, reauthenticate or attest, repair correlation, and review delegated capabilities.
Excessive delegation	A principal transfers broader or longer authority than intended.	Revoke grants, narrow policy, require approval, and inspect prior activity.
State divergence	Offline, distributed, or cached copies disagree with authority.	Enter reconciliation, preserve conflicting versions, and prevent unsafe promotion.
Evidence break	Records cannot prove sequence, identity, integrity, or final state.	Classify result as unassured and restore instrumentation before resuming.
Learning manipulation	Assessment, skill graph, or adaptive path is gamed or biased.	Review evidence, recalibrate, require alternate assessment, and provide appeal.
Privacy over-retention	Memory, embeddings, traces, or credentials persist beyond purpose.	Delete, revoke, rebuild derived indexes, and document residual copies.

Minimum evidence by decision domain

DECISION DOMAIN	MINIMUM EVIDENCE
Grounded answer	Claim-to-source mapping, source authority, freshness, retrieval trace, conflicts, and confidence.
State transition	Prior state, command or event, authenticated principal, policy decision, resulting state, and verification.
Identity issuance	Proofing method, authenticator or workload attestation, issuer, policy, validity, and revocation path.
Authorization	Principal, attributes, resource, action, context, policy version, decision, obligations, and expiration.
Memory write	Source, purpose, scope, confidence, sensitivity, owner, expiration, correction, and deletion semantics.
Credential award	Competency, rubric, assessment evidence, evaluator, issuer, issue date, validity, and revocation.
Data movement	Classification, source, destination, purpose, legal or policy basis, transformation, egress decision, and retention.
Exception	Control, rationale, risk, compensating controls, owner, approval, expiration, and review result.

Implementation roadmap

PHASE	FOCUS	EXIT CONDITION
1. Authority model	Source classes, ownership, exact versions, freshness, and conflict policy.	Approved authority registry and review cadence.
2. Identity substrate	Human, workload, agent, device, and extension identity with lifecycle and attestation.	End-to-end principal correlation and revocation demonstration.
3. State and evidence	Authoritative models, durable events, integrity, replay, and evidence bundles.	Recovery and reconstruction tests pass.
4. Knowledge and memory	Grounded retrieval, provenance, memory scopes, correction, deletion, and contradiction handling.	Poisoning, stale-source, and privacy tests pass.
5. Learning assurance	Skill graphs, accessible labs, authentic assessments, and verifiable credentials.	Evidence-backed credential issuance and appeal process.
6. Continuous governance	Metrics, incidents, exceptions, audits, source expiration, and revalidation.	Operating owners accept SLOs and review obligations.

Assurance conclusion

Knowledge informs decisions; identity establishes the actor; policy constrains authority; data records state; evidence makes outcomes reviewable; learning changes capability under transparent and measurable governance. Weakness in any one layer limits the assurance of the entire system.

CANONICAL LIVING OVERVIEW GUIDE

AI Model Architecture and Capability Foundations

A foundation-to-frontier guide covering tensors, representation learning, transformers, attention, encoders, decoders, mixture-of-experts, diffusion, state-space and recurrent alternatives, multimodality, scaling, capability boundaries, and architecture evaluation.

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-SWE; MYTHOS-DAT; MYTHOS-EMT
Audience	AI engineers, software architects, technical leaders, evaluators, infrastructure engineers, and advanced practitioners.
Prerequisites	Linear algebra, probability, software engineering, data structures, and basic machine-learning concepts.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Explain model computation from tensors and embeddings through attention, layers, logits, and decoding.

Differentiate encoder, decoder, encoder-decoder, diffusion, MoE, recurrent, and multimodal architectures.

Connect architecture choices to capability, context, latency, memory, training, and failure behavior.

Identify the difference between model capability and complete AI-system capability.

Evaluate architecture claims through controlled tasks, ablations, profiles, and limitations.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Mathematical and computational foundations

Build the minimum model of tensor computation, optimization, and representation.

Chapter operating position
Build the minimum model of tensor computation, optimization, and representation.

1.1 Tensors, shapes, and linear transforms

Tensors, shapes, and linear transforms must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Trace batches, sequence, hidden dimensions, heads, matrices, broadcasting, and device placement. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tensors, shapes, and linear transforms.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating tensors, shapes, and linear transforms as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tensors, shapes, and linear transforms.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Embeddings and representations

Embeddings and representations must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Understand token, position, segment, modality, and learned representation spaces. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for embeddings and representations.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

Treating embeddings and representations as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for embeddings and representations.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Probability and logits

Probability and logits must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Relate logits, softmax, likelihood, entropy, calibration, and sampling. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for probability and logits.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating probability and logits as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for probability and logits.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Optimization and gradients

Optimization and gradients must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Explain loss, backpropagation, optimizers, schedules, regularization, precision, and distributed updates. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for optimization and gradients.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating optimization and gradients as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for optimization and gradients.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Implement a small tensor classifier and inspect shapes, gradients, calibration, and failure under distribution shift.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore low-precision training, learned optimizers, and alternative computational substrates.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Transformer and attention architecture

Understand the dominant sequence-model architecture at implementation level.

Chapter operating position
Understand the dominant sequence-model architecture at implementation level.

2.1 Self-attention

Self-attention must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Trace query, key, value projection, scores, masking, normalization, weighted values, and head composition. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for self-attention.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating self-attention as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for self-attention.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Feed-forward and normalization blocks

Feed-forward and normalization blocks must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Understand residual streams, normalization placement, activations, gating, and depth. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for feed-forward and normalization blocks.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

- Treating feed-forward and normalization blocks as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for feed-forward and normalization blocks.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Position and sequence representation

Position and sequence representation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare absolute, relative, rotary, bias-based, and recurrent context mechanisms. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for position and sequence representation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating position and sequence representation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for position and sequence representation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Efficient attention variants

Efficient attention variants must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate grouped-query, multi-query, sparse, sliding-window, linear, and IO-aware attention. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for efficient attention variants.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating efficient attention variants as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for efficient attention variants.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Build a tiny transformer and compare full, causal, and local attention masks with profiling.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore adaptive attention, recurrent memory, state-space models, and learned compute allocation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Encoder, decoder, and sequence-to-sequence families

Match model family to representation, generation, and transformation tasks.

Chapter operating position
Match model family to representation, generation, and transformation tasks.

3.1 Encoder-only models

Encoder-only models must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use bidirectional context for classification, retrieval, extraction, and embedding. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for encoder-only models.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating encoder-only models as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for encoder-only models.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 Decoder-only models

Decoder-only models must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use causal prediction for generation, in-context learning, tools, and autoregressive multimodality. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for decoder-only models.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

Treating decoder-only models as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for decoder-only models.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Encoder-decoder models

Encoder-decoder models must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate source representation from conditional generation for translation and transformation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for encoder-decoder models.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating encoder-decoder models as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for encoder-decoder models.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Prefix, infill, and structured generation

Prefix, infill, and structured generation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Support code completion, editing, constrained output, and bidirectional context patterns. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prefix, infill, and structured generation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating prefix, infill, and structured generation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prefix, infill, and structured generation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Compare tiny encoder, decoder, and encoder-decoder models on classification and sequence transformation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore universal architectures that dynamically select encoding and generation modes.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Mixture-of-experts and conditional computation

Understand sparse capacity, routing, and operational tradeoffs.

Chapter operating position
Understand sparse capacity, routing, and operational tradeoffs.

4.1 Experts and routers

Experts and routers must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Trace token routing, top-k selection, expert computation, residual paths, and output combination. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for experts and routers.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating experts and routers as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for experts and routers.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Load balancing and specialization

Load balancing and specialization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control expert collapse, capacity, dropped tokens, auxiliary losses, and specialization. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for load balancing and specialization.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

Treating load balancing and specialization as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for load balancing and specialization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Distributed execution

Distributed execution must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Place experts across devices, manage all-to-all communication, memory, latency, and failures. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for distributed execution.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating distributed execution as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for distributed execution.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Capability and evaluation

Capability and evaluation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Distinguish parameter count, active parameters, routing quality, and domain performance. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capability and evaluation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating capability and evaluation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capability and evaluation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Implement a small routed expert layer and measure balance, specialization, latency, and failure when one expert is unavailable.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore hierarchical experts, dynamic depth, modular skill composition, and expert marketplaces.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Generative architectures beyond text transformers

Connect diffusion, autoregressive, masked, and latent generative systems.

Chapter operating position
Connect diffusion, autoregressive, masked, and latent generative systems.

5.1 Diffusion and denoising

Diffusion and denoising must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Understand forward corruption, reverse denoising, score prediction, schedules, guidance, and sampling. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for diffusion and denoising.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating diffusion and denoising as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for diffusion and denoising.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Autoregressive media generation

Autoregressive media generation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Generate image, audio, video, or actions as discrete or continuous sequences. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for autoregressive media generation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

Treating autoregressive media generation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for autoregressive media generation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Latent representations

Latent representations must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use autoencoders, tokenizers, compressed spaces, and modality-specific decoders. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for latent representations.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating latent representations as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for latent representations.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Consistency, flow, and accelerated sampling

Consistency, flow, and accelerated sampling must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate fewer-step generation, distillation, flow matching, and quality tradeoffs. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for consistency, flow, and accelerated sampling.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating consistency, flow, and accelerated sampling as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for consistency, flow, and accelerated sampling.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory

Implement a one-dimensional diffusion toy model and compare sampling steps, noise schedules, and reconstruction error.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore unified world models, continuous-time models, and multimodal generative simulators.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Multimodal and embodied architectures

Fuse text, image, audio, video, sensor, and action representations.

Chapter operating position
Fuse text, image, audio, video, sensor, and action representations.

6.1 Modality encoders and tokenization

Modality encoders and tokenization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Represent patches, frames, spectrograms, waveforms, sensors, and actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for modality encoders and tokenization.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating modality encoders and tokenization as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for modality encoders and tokenization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Fusion and cross-attention

Fusion and cross-attention must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare early, late, shared-space, cross-attention, and adapter-based fusion. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for fusion and cross-attention.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

Treating fusion and cross-attention as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for fusion and cross-attention.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Grounding and temporal understanding

Grounding and temporal understanding must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Link language to regions, timestamps, speakers, objects, actions, and environment state. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for grounding and temporal understanding.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating grounding and temporal understanding as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for grounding and temporal understanding.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Embodied and world-model loops

Embodied and world-model loops must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Connect perception, memory, planning, control, feedback, and safety. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for embodied and world-model loops.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating embodied and world-model loops as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for embodied and world-model loops.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Build a small paired image-text embedding system and evaluate retrieval, hard negatives, and calibration.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore realtime world models, spatial intelligence, and physical AI foundation models.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Scaling, emergence, and capability boundaries

Interpret scaling evidence without treating model size as a complete capability measure.

Chapter operating position
Interpret scaling evidence without treating model size as a complete capability measure.

7.1 Scaling variables

Scaling variables must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Relate parameters, data, compute, tokens, architecture, optimizer, precision, and training quality. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for scaling variables.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating scaling variables as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for scaling variables.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 In-context learning and adaptation

In-context learning and adaptation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Distinguish memorization, pattern induction, retrieval, reasoning, and tool-mediated behavior. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for in-context learning and adaptation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

- Treating in-context learning and adaptation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for in-context learning and adaptation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Capability discontinuities and measurement

Capability discontinuities and measurement must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Investigate threshold effects, benchmark artifacts, contamination, prompting, and confidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capability discontinuities and measurement.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating capability discontinuities and measurement as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capability discontinuities and measurement.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 System capability versus model capability

System capability versus model capability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate weights from retrieval, tools, memory, orchestration, policy, and user interface. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for system capability versus model capability.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating system capability versus model capability as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for system capability versus model capability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory
Run scaling experiments on small models and identify which apparent capability gains are data, prompt, or metric artifacts.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore test-time compute, adaptive reasoning, modular networks, and self-improving systems.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Architecture selection and assurance

Choose model architecture according to workload, evidence, and constraints.

Chapter operating position
Choose model architecture according to workload, evidence, and constraints.

8.1 Workload and capability matrix

Workload and capability matrix must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Map tasks, modalities, context, latency, throughput, privacy, adaptation, and deployment. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for workload and capability matrix.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating workload and capability matrix as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for workload and capability matrix.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Resource and lifecycle model

Resource and lifecycle model must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Estimate training, inference, memory, storage, networking, updates, evaluation, and operations. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for resource and lifecycle model.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
class TinyAttention(torch.nn.Module):
    def __init__(self, width: int, heads: int):
        super().__init__()
        assert width % heads == 0
        self.heads = heads
        self.qkv = torch.nn.Linear(width, width * 3)
        self.out = torch.nn.Linear(width, width)

    def forward(self, x, causal_mask):
        q, k, v = self.qkv(x).chunk(3, dim=-1)
        # reshape -> attention -> merge; see reference project
        return self.out(attend(q, k, v, causal_mask, self.heads))
```

Failure patterns

Treating resource and lifecycle model as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for resource and lifecycle model.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Risk and failure analysis

Risk and failure analysis must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Assess hallucination, bias, brittleness, privacy, security, misuse, uncertainty, and unsafe autonomy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for risk and failure analysis.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating risk and failure analysis as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for risk and failure analysis.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Architecture decision record

Architecture decision record must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Document alternatives, evidence, assumptions, limitations, selection, review triggers, and exit. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the input representation, model block, state, output distribution, decoding, system integration, evaluation, and limitation chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for architecture decision record.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating architecture decision record as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for architecture decision record.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Create an architecture decision for an enterprise assistant using at least four model families and explicit system components.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore architecture search guided by safety, energy, sovereignty, and measurable system outcomes.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Candidate Focused Field Guide

Review date
2026-10-26

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-DAT; MYTHOS-SEC; MYTHOS-SWE
Audience	AI evaluators, model engineers, product teams, security teams, agent architects, and governance leaders.
Prerequisites	Statistics, experimentation, AI systems, software testing, data governance, and risk fundamentals.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Design evaluations around decisions, users, failure costs, and deployment conditions.

Measure model and agent capability, safety, robustness, calibration, efficiency, and operational behavior.

Build reproducible datasets, rubrics, graders, sandboxes, and regression suites.

Identify contamination, judge bias, leakage, overfitting, and misleading aggregate scores.

Convert evaluation evidence into release, routing, monitoring, and retirement decisions.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Evaluation strategy and decision context

Define what decision the evaluation must support.

Chapter operating position
Define what decision the evaluation must support.

1.1 Use case and stakeholder outcomes

Use case and stakeholder outcomes must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Specify users, tasks, environments, consequences, risk tolerance, and acceptable failure. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for use case and stakeholder outcomes.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating use case and stakeholder outcomes as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for use case and stakeholder outcomes.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Model, system, and agent boundaries

Model, system, and agent boundaries must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate base model, prompting, retrieval, tools, memory, policies, interface, and human oversight. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for model, system, and agent boundaries.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating model, system, and agent boundaries as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for model, system, and agent boundaries.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Evaluation dimensions

Evaluation dimensions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Select correctness, relevance, safety, robustness, calibration, latency, cost, privacy, and accessibility. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for evaluation dimensions.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating evaluation dimensions as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for evaluation dimensions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Release and routing decisions

Release and routing decisions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define pass, conditional release, restricted use, fallback, monitoring, and retirement criteria. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for release and routing decisions.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating release and routing decisions as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for release and routing decisions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Create an evaluation charter for an agentic application and identify decisions that cannot be supported by one benchmark.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore continuously updated decision-centric evaluation graphs.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Datasets, tasks, and contamination control

Create representative, lawful, and defensible evaluation material.

Chapter operating position
Create representative, lawful, and defensible evaluation material.

2.1 Task and scenario design

Task and scenario design must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Sample nominal, edge, adversarial, multilingual, multimodal, long-context, and failure scenarios. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for task and scenario design.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating task and scenario design as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for task and scenario design.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Ground truth and reference answers

Ground truth and reference answers must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use deterministic results, expert labels, accepted ranges, process criteria, or evidence-based rubrics. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for ground truth and reference answers.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating ground truth and reference answers as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for ground truth and reference answers.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Splits and hidden tests

Splits and hidden tests must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate development, validation, public benchmark, private holdout, and incident-derived cases. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for splits and hidden tests.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating splits and hidden tests as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for splits and hidden tests.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Contamination and leakage

Contamination and leakage must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect memorization, benchmark exposure, prompt leakage, judge leakage, and iterative overfitting. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for contamination and leakage.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating contamination and leakage as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for contamination and leakage.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Build a hidden evaluation set with provenance, difficulty strata, adversarial variants, and contamination checks.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore renewable benchmarks and private cryptographic evaluation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Metrics, scoring, and uncertainty

Choose measurements that reflect actual quality and risk.

Chapter operating position
Choose measurements that reflect actual quality and risk.

3.1 Exact and semantic metrics

Exact and semantic metrics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use accuracy, F1, ranking, retrieval, similarity, structured validity, and task-specific measures appropriately. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for exact and semantic metrics.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating exact and semantic metrics as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for exact and semantic metrics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 Rubrics and partial credit

Rubrics and partial credit must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define observable criteria, severity, critical failures, weighting, and inter-rater agreement. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for rubrics and partial credit.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating rubrics and partial credit as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for rubrics and partial credit.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Calibration and confidence

Calibration and confidence must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure probability quality, selective answering, abstention, confidence, and coverage-risk curves. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for calibration and confidence.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating calibration and confidence as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for calibration and confidence.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Statistical uncertainty

Statistical uncertainty must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Report sample size, confidence intervals, effect sizes, variance, dependence, and practical significance. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for statistical uncertainty.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating statistical uncertainty as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for statistical uncertainty.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Compare three metrics on the same outputs and show how ranking changes under critical-error weighting and uncertainty.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore utility-based evaluation and causal estimates of deployment impact.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Automated graders and model judges

Use scalable grading without hiding judge error and bias.

Chapter operating position
Use scalable grading without hiding judge error and bias.

4.1 Deterministic validators

Deterministic validators must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Check schemas, code execution, tests, calculations, citations, policies, and state transitions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for deterministic validators.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating deterministic validators as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for deterministic validators.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Model-based judging

Model-based judging must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Design rubrics, references, pairwise comparisons, blinded order, multi-judge panels, and disagreement handling. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for model-based judging.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating model-based judging as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for model-based judging.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Judge validation

Judge validation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure correlation with experts, positional bias, verbosity bias, self-preference, contamination, and adversarial manipulation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for judge validation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating judge validation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for judge validation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Grader security and isolation

Grader security and isolation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Treat evaluated outputs as untrusted, sandbox execution, limit tools, and prevent prompt injection. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for grader security and isolation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating grader security and isolation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for grader security and isolation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Validate a model judge against expert labels and adversarial outputs, then define where it may and may not make decisions.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore proof-carrying outputs and ensembles of specialized verifier models.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Agent, tool, and long-horizon evaluation

Measure trajectory quality, state, recovery, and verified completion.

Chapter operating position
Measure trajectory quality, state, recovery, and verified completion.

5.1 Task environment and sandbox

Task environment and sandbox must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define initial state, tools, permissions, hidden checks, time, budget, reset, and isolation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for task environment and sandbox.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating task environment and sandbox as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for task environment and sandbox.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Trajectory and decision quality

Trajectory and decision quality must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Record observations, plans, actions, tool arguments, state changes, evidence, retries, and corrections. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for trajectory and decision quality.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating trajectory and decision quality as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for trajectory and decision quality.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Completion and side effects

Completion and side effects must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Verify requested outcomes, prohibited actions, resource use, residual changes, cleanup, and rollback. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for completion and side effects.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating completion and side effects as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for completion and side effects.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Long-horizon reliability

Long-horizon reliability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure compounding error, context loss, looping, premature completion, recovery, and supervisor effectiveness. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for long-horizon reliability.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating long-horizon reliability as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for long-horizon reliability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory

Evaluate an agent on a repository task with hidden tests, injected tool failure, stale context, and a prohibited action.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore standardized agent environments and causal trajectory evaluation.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Safety, security, and robustness evaluation

Test harms and failures under realistic pressure.

Chapter operating position
Test harms and failures under realistic pressure.

6.1 Misuse and harmful capability

Misuse and harmful capability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate assistance, autonomy, scale, access, safeguards, and human controls according to use case. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for misuse and harmful capability.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating misuse and harmful capability as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for misuse and harmful capability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Prompt injection and data exfiltration

Prompt injection and data exfiltration must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test direct and indirect injection, tool output, retrieval documents, memory, and cross-tenant boundaries. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompt injection and data exfiltration.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

Treating prompt injection and data exfiltration as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompt injection and data exfiltration.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Robustness and distribution shift

Robustness and distribution shift must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Vary wording, language, modality, noise, missing context, user expertise, and operational conditions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for robustness and distribution shift.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating robustness and distribution shift as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for robustness and distribution shift.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Privacy and memorization

Privacy and memorization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test sensitive data reproduction, membership signals, retention, logging, and user control. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for privacy and memorization.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating privacy and memorization as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for privacy and memorization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Build an adversarial suite covering prompt injection, tool misuse, private data, policy conflict, and degraded dependencies.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore mechanism-based jailbreak benchmarks and adaptive red-teaming.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Performance, efficiency, and service evaluation

Measure the deployed system rather than model quality alone.

Chapter operating position
Measure the deployed system rather than model quality alone.

7.1 Latency decomposition

Latency decomposition must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure queue, prefill, decode, tool, retrieval, network, postprocessing, and user-perceived latency. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for latency decomposition.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating latency decomposition as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for latency decomposition.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Throughput and concurrency

Throughput and concurrency must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure requests, tokens, batches, saturation, tail latency, fairness, and overload. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for throughput and concurrency.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating throughput and concurrency as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for throughput and concurrency.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Resource and cost

Resource and cost must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Track compute, memory, cache, storage, networking, energy, provider cost, and operator effort. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for resource and cost.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating resource and cost as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for resource and cost.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Reliability and availability

Reliability and availability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test timeouts, retries, fallbacks, model failure, dependency failure, rate limits, and disaster recovery. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for reliability and availability.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating reliability and availability as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for reliability and availability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory

Benchmark an AI service under mixed prompt lengths and concurrency, reporting quality, tail latency, throughput, cost, and failures.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore energy- and carbon-aware inference evaluation and adaptive service routing.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Evaluation operations and governance

Keep evaluation fresh, reproducible, and connected to lifecycle decisions.

Chapter operating position
Keep evaluation fresh, reproducible, and connected to lifecycle decisions.

8.1 Evaluation as code

Evaluation as code must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Version tasks, data, graders, environments, model config, seeds, dependencies, and reports. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for evaluation as code.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating evaluation as code as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for evaluation as code.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Regression and canary evaluation

Regression and canary evaluation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Run pre-merge, nightly, release, shadow, canary, and post-incident suites with comparison thresholds. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for regression and canary evaluation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
evaluation_case:
  id: repo-change-042
  system_version: agent-stack-1.4
  hidden_checks:
    - tests
    - prohibited-side-effects
    - citation-support
  metrics:
    - task_success
    - critical_failure_count
    - latency_ms
    - tool_calls
    - human_review_minutes
  decision:
    release_only_if: critical_failure_count == 0
```

Failure patterns

- Treating regression and canary evaluation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for regression and canary evaluation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Evidence and reporting

Evidence and reporting must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Publish per-slice results, critical failures, uncertainty, limitations, artifacts, decision, and owner. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for evidence and reporting.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating evidence and reporting as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for evidence and reporting.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Monitoring and refresh

Monitoring and refresh must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Add production failures, detect benchmark saturation, rotate hidden tests, and revisit risk assumptions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the decision, scenario, dataset, system configuration, run, grader, metric, uncertainty, finding, and lifecycle action chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for monitoring and refresh.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating monitoring and refresh as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for monitoring and refresh.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Create a CI evaluation pipeline with hidden cases, slice reports, regression thresholds, artifact retention, and release decisions.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop self-refreshing evaluation systems governed by source authority and human review.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. NIST - Artificial Intelligence Risk Management Framework 1.0

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Status
Candidate Focused Field Guide

Review date
2026-10-26

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-EMT; MYTHOS-SEC; MYTHOS-CLD
Audience	AI platform engineers, desktop developers, security teams, sovereign-infrastructure architects, and local-model practitioners.
Prerequisites	AI model fundamentals, operating systems, hardware, software packaging, security, and inference concepts.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Select local models and runtimes according to capability, hardware, licensing, privacy, and operational needs.

Size CPU, GPU, NPU, memory, storage, context, and throughput realistically.

Operate models offline with verified artifacts, controlled updates, and reproducible configuration.

Design sovereign and hybrid AI architectures with explicit data, identity, egress, and fallback boundaries.

Evaluate local systems on representative tasks, resource limits, privacy, and recovery.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Local and sovereign AI architecture

Define why inference is local and which trust boundaries change.

Chapter operating position
Define why inference is local and which trust boundaries change.

1.1 Local, edge, private, and sovereign modes

Local, edge, private, and sovereign modes must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Differentiate on-device, workstation, site, private cloud, air-gapped, national, and hybrid execution. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for local, edge, private, and sovereign modes.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating local, edge, private, and sovereign modes as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for local, edge, private, and sovereign modes.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Data and egress boundaries

Data and egress boundaries must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control prompts, files, embeddings, telemetry, model calls, updates, licenses, and support data. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for data and egress boundaries.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating data and egress boundaries as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for data and egress boundaries.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Identity and policy

Identity and policy must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Authorize users, applications, models, tools, data, and administrative actions locally. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for identity and policy.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating identity and policy as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for identity and policy.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Availability and survivability

Availability and survivability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Plan offline operation, dependency removal, degraded modes, backups, and recovery. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for availability and survivability.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating availability and survivability as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for availability and survivability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Create a sovereign AI architecture for a sensitive workflow and prove which information can and cannot leave each boundary.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore verifiable sovereign AI appliances and federated local model fabrics.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Model selection, licensing, and artifact trust

Choose a model as a governed software and data artifact.

Chapter operating position
Choose a model as a governed software and data artifact.

2.1 Capability and task fit

Capability and task fit must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare reasoning, coding, extraction, retrieval, multilingual, multimodal, tool use, and structured output. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capability and task fit.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating capability and task fit as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capability and task fit.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Licensing and acceptable use

Licensing and acceptable use must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Review model license, weights, derivatives, redistribution, commercial use, dataset obligations, and policy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for licensing and acceptable use.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating licensing and acceptable use as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for licensing and acceptable use.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Artifact formats and metadata

Artifact formats and metadata must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Understand checkpoints, safetensors, GGUF, ONNX, tokenizers, chat templates, adapters, and configuration. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for artifact formats and metadata.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating artifact formats and metadata as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for artifact formats and metadata.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Integrity and provenance

Integrity and provenance must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Verify source, hashes, signatures, conversion, quantization, model card, tests, and trusted distribution. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for integrity and provenance.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating integrity and provenance as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for integrity and provenance.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Qualify two local models through license, artifact, tokenizer, conversion, capability, safety, and provenance review.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore signed model bills of materials and transparency logs for weight artifacts.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Hardware sizing and execution backends

Map model architecture and precision to real device resources.

Chapter operating position
Map model architecture and precision to real device resources.

3.1 Memory budgeting

Memory budgeting must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Estimate weights, KV cache, activations, runtime buffers, context, batch, multimodal encoders, and fragmentation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for memory budgeting.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating memory budgeting as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for memory budgeting.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 CPU, GPU, NPU, and accelerator paths

CPU, GPU, NPU, and accelerator paths must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare cores, vector units, memory bandwidth, VRAM, unified memory, device transfer, and supported operators. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for cpu, gpu, npu, and accelerator paths.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

Treating cpu, gpu, npu, and accelerator paths as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for cpu, gpu, npu, and accelerator paths.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Backend selection

Backend selection must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate llama.cpp, ONNX Runtime, MLX, vendor runtimes, containers, and native application integration. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for backend selection.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating backend selection as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for backend selection.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Thermal, power, and sustained performance

Thermal, power, and sustained performance must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure clocks, throttling, fan, battery, heat, energy, and long-running stability. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for thermal, power, and sustained performance.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating thermal, power, and sustained performance as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for thermal, power, and sustained performance.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Create a hardware-fit estimator and validate predicted memory and throughput against two precisions and context lengths.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore disaggregated memory, chiplets, photonic interconnects, and adaptive CPU/GPU/NPU execution.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Quantization and local optimization

Reduce footprint while measuring quality and platform effects.

Chapter operating position
Reduce footprint while measuring quality and platform effects.

4.1 Weight precision and formats

Weight precision and formats must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare FP16, BF16, FP8, INT8, INT4, mixed precision, group size, scales, and zero points. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for weight precision and formats.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating weight precision and formats as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for weight precision and formats.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Post-training and calibration

Post-training and calibration must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use representative calibration, clipping, outlier treatment, error metrics, and task evaluation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for post-training and calibration.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating post-training and calibration as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for post-training and calibration.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 KV-cache and activation optimization

KV-cache and activation optimization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Adjust cache precision, context, batching, offload, flash attention, and memory layout. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for kv-cache and activation optimization.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating kv-cache and activation optimization as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for kv-cache and activation optimization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Quality and performance verification

Quality and performance verification must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure task accuracy, structured output, perplexity limits, latency, throughput, memory, and power. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for quality and performance verification.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating quality and performance verification as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for quality and performance verification.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Quantize a small model or simulate quantization and compare memory, latency, and task quality across precisions.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore adaptive per-layer quantization and runtime quality-aware precision.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Runtime, session, and application integration

Embed local inference into reliable desktop, mobile, and edge applications.

Chapter operating position
Embed local inference into reliable desktop, mobile, and edge applications.

5.1 Model loading and lifecycle

Model loading and lifecycle must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Manage discovery, validation, loading, warmup, unload, updates, rollback, and concurrent access. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for model loading and lifecycle.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating model loading and lifecycle as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for model loading and lifecycle.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Prompt and chat templates

Prompt and chat templates must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control system messages, roles, tokens, special tokens, tool schemas, stops, and model-specific formats. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompt and chat templates.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating prompt and chat templates as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompt and chat templates.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Streaming and cancellation

Streaming and cancellation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Deliver tokens, progress, backpressure, user cancellation, timeouts, and cleanup. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for streaming and cancellation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating streaming and cancellation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for streaming and cancellation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Isolation and resource governance

Isolation and resource governance must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Limit files, network, memory, CPU, GPU, tools, processes, and tenant sharing. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for isolation and resource governance.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating isolation and resource governance as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for isolation and resource governance.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory

Build a local inference session manager with model validation, streaming, cancellation, resource limits, and safe unload.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore OS-native AI runtimes and capability-isolated local agent containers.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Offline knowledge, tools, and updates

Operate useful AI systems without assuming permanent cloud services.

Chapter operating position
Operate useful AI systems without assuming permanent cloud services.

6.1 Local retrieval and memory

Local retrieval and memory must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Store documents, indexes, embeddings, metadata, citations, and user-controlled memory locally. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for local retrieval and memory.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating local retrieval and memory as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for local retrieval and memory.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Local tools and automation

Local tools and automation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Expose filesystem, search, code, databases, devices, and workflows through least-privilege interfaces. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for local tools and automation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating local tools and automation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for local tools and automation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Update distribution

Update distribution must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use signed model, runtime, index, policy, and tool updates with staged rollout and rollback. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for update distribution.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating update distribution as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for update distribution.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Air-gap transfer and scanning

Air-gap transfer and scanning must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control removable media, manifests, hashes, malware scanning, quarantine, approval, and import evidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for air-gap transfer and scanning.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating air-gap transfer and scanning as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for air-gap transfer and scanning.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory

Design an offline update bundle containing model, runtime, index, policy, and tool changes with complete verification and rollback.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore delay-tolerant synchronization and content-addressed sovereign AI distribution.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Privacy, security, and operational assurance

Prove that local execution delivers the intended trust benefit.

Chapter operating position
Prove that local execution delivers the intended trust benefit.

7.1 Threat modeling

Threat modeling must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Assess local users, malware, administrators, model files, prompt injection, tools, memory, telemetry, and physical access. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for threat modeling.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating threat modeling as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for threat modeling.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Data protection

Data protection must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use OS isolation, encryption, access control, secure deletion, logging, retention, and user-visible controls. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for data protection.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating data protection as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for data protection.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Model and tool security

Model and tool security must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test malicious models, parsers, templates, plugins, prompts, indirect injection, and unsafe actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for model and tool security.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating model and tool security as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for model and tool security.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Incident and recovery

Incident and recovery must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Revoke models or tools, preserve evidence, restore trusted artifacts, rotate secrets, and validate state. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for incident and recovery.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating incident and recovery as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for incident and recovery.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory

Red-team a local AI application for artifact tampering, prompt injection, tool misuse, memory leakage, and telemetry egress.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore attested local inference and encrypted model execution.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Evaluation, routing, and hybrid architecture

Decide when local, private, or cloud models should handle work.

Chapter operating position
Decide when local, private, or cloud models should handle work.

8.1 Representative task evaluation

Representative task evaluation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure capability, safety, privacy, latency, throughput, context, reliability, and structured output. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for representative task evaluation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating representative task evaluation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for representative task evaluation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Hardware-aware model routing

Hardware-aware model routing must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Route by task, model fit, memory, current load, deadline, energy, and privacy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for hardware-aware model routing.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
local_route:
  privacy_class: restricted
  preferred_runtime: llama.cpp
  artifact:
    format: gguf
    sha256: required
    license_review: required
  limits:
    ram_gib: 32
    context_tokens: 32768
    max_parallel: 2
  fallback:
    remote_allowed: false
  telemetry:
    content_logging: disabled
```

Failure patterns

- Treating hardware-aware model routing as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for hardware-aware model routing.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Hybrid escalation

Hybrid escalation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define when data may be minimized, summarized, redacted, or approved for stronger remote models. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for hybrid escalation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating hybrid escalation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for hybrid escalation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Lifecycle and retirement

Lifecycle and retirement must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Monitor model quality, vulnerabilities, licensing, runtime compatibility, replacements, and archived evidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the artifact, license, hardware, runtime, context, inference, tool or knowledge boundary, telemetry, update, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for lifecycle and retirement.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating lifecycle and retirement as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for lifecycle and retirement.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Create and test a local-first router with privacy classes, capability thresholds, resource limits, fallback, and user approval.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore distributed personal model ensembles and privacy-preserving collaborative inference.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. Hugging Face - GGUF Documentation

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-CLD; MYTHOS-DAT; MYTHOS-SWE
Audience	AI infrastructure, performance, platform, cloud, SRE, and model-serving engineers.
Prerequisites	Model architecture, GPU computing, distributed systems, performance engineering, networking, and observability.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Decompose inference latency, memory, throughput, and quality across the complete service path.

Engineer batching, scheduling, KV-cache, prefix reuse, and parallelism for mixed workloads.

Select quantization and speculative techniques through measured quality and hardware evidence.

Operate scalable inference services with SLOs, admission control, observability, and recovery.

Benchmark and optimize without hiding queueing, tail latency, failures, or cost.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Inference request and execution pipeline

Trace work from request admission through generated output.

Chapter operating position
Trace work from request admission through generated output.

1.1 Request validation and tokenization

Request validation and tokenization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Validate model, parameters, schema, prompt size, special tokens, tools, and tenant policy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for request validation and tokenization.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating request validation and tokenization as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for request validation and tokenization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Prefill and decode

Prefill and decode must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate prompt processing from iterative token generation and identify compute and memory bottlenecks. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prefill and decode.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating prefill and decode as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prefill and decode.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Sampling and structured output

Sampling and structured output must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Implement temperature, top-k, top-p, penalties, stops, constrained decoding, and validation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for sampling and structured output.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating sampling and structured output as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for sampling and structured output.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Streaming and completion

Streaming and completion must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Deliver ordered chunks, usage, finish reasons, cancellation, final validation, and cleanup. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for streaming and completion.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating streaming and completion as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for streaming and completion.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Instrument a small inference pipeline and measure tokenization, prefill, decode, streaming, and postprocessing independently.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore semantic decoding accelerators and hardware-native structured generation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Memory architecture and KV cache

Understand the dominant state retained during autoregressive generation.

Chapter operating position
Understand the dominant state retained during autoregressive generation.

2.1 KV-cache shape and growth

KV-cache shape and growth must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Relate layers, heads, head dimension, sequence, batch, precision, and model architecture. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for kv-cache shape and growth.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating kv-cache shape and growth as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for kv-cache shape and growth.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Paged allocation and fragmentation

Paged allocation and fragmentation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use blocks, free lists, eviction, reuse, and scheduling to improve memory utilization. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for paged allocation and fragmentation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating paged allocation and fragmentation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for paged allocation and fragmentation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Prefix and session reuse

Prefix and session reuse must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Share stable prefixes safely across requests, tenants, adapters, and model versions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prefix and session reuse.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating prefix and session reuse as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prefix and session reuse.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Quantized and offloaded cache

Quantized and offloaded cache must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Trade memory, bandwidth, latency, quality, CPU, GPU, and distributed storage. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for quantized and offloaded cache.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating quantized and offloaded cache as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for quantized and offloaded cache.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Build a KV-cache estimator and simulate fragmentation, prefix reuse, eviction, and precision changes.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore distributed persistent caches and learned cache retention.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Batching, scheduling, and admission control

Maximize useful throughput while protecting interactive latency and fairness.

Chapter operating position
Maximize useful throughput while protecting interactive latency and fairness.

3.1 Static and continuous batching

Static and continuous batching must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare request grouping, iteration-level scheduling, padding, utilization, and tail latency. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for static and continuous batching.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating static and continuous batching as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for static and continuous batching.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 Workload classes and priorities

Workload classes and priorities must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate interactive, batch, long-context, tool, multimodal, and background requests. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for workload classes and priorities.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating workload classes and priorities as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for workload classes and priorities.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Admission and overload

Admission and overload must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use token budgets, queue limits, deadlines, reservations, rejection, degradation, and backpressure. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for admission and overload.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating admission and overload as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for admission and overload.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Fairness and tenant isolation

Fairness and tenant isolation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Prevent large prompts, long outputs, retries, and priority users from starving others. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for fairness and tenant isolation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating fairness and tenant isolation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for fairness and tenant isolation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Simulate a continuous batching scheduler under mixed prompt and output lengths, then evaluate fairness and tail latency.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore reinforcement-learned schedulers constrained by SLO and cost policy.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Quantization and numerical deployment

Reduce memory and improve throughput without assuming equal quality across workloads.

Chapter operating position
Reduce memory and improve throughput without assuming equal quality across workloads.

4.1 Weight, activation, and KV precision

Weight, activation, and KV precision must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare FP16, BF16, FP8, INT8, INT4, mixed, weight-only, activation-aware, and cache quantization. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for weight, activation, and kv precision.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating weight, activation, and kv precision as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for weight, activation, and kv precision.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Calibration and outliers

Calibration and outliers must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Select representative data, scales, groups, clipping, smoothness, and per-layer treatment. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for calibration and outliers.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating calibration and outliers as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for calibration and outliers.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Kernel and hardware compatibility

Kernel and hardware compatibility must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Match formats to compute capability, tensor cores, vector units, compilers, and serving engines. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for kernel and hardware compatibility.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating kernel and hardware compatibility as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for kernel and hardware compatibility.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Quality validation

Quality validation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate language, code, reasoning, structured output, multilingual, multimodal, safety, and rare failures. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for quality validation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating quality validation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for quality validation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Create a quantization acceptance matrix with memory, throughput, latency, and task-quality gates.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore online adaptive quantization and precision allocation per request.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Parallelism and distributed serving

Scale models and replicas across devices and nodes.

Chapter operating position
Scale models and replicas across devices and nodes.

5.1 Tensor and pipeline parallelism

Tensor and pipeline parallelism must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Split layers and tensor operations while managing communication, bubbles, topology, and failure. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tensor and pipeline parallelism.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating tensor and pipeline parallelism as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tensor and pipeline parallelism.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Expert and sequence parallelism

Expert and sequence parallelism must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Distribute MoE experts or sequence work and manage routing, all-to-all, and imbalance. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for expert and sequence parallelism.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating expert and sequence parallelism as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for expert and sequence parallelism.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Data parallel replicas

Data parallel replicas must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Route requests, share adapters or caches, scale horizontally, and isolate failures. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for data parallel replicas.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating data parallel replicas as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for data parallel replicas.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Disaggregated prefill and decode

Disaggregated prefill and decode must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate compute phases, transfer cache state, and evaluate network and scheduling overhead. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for disaggregated prefill and decode.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating disaggregated prefill and decode as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for disaggregated prefill and decode.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory
Model tensor, pipeline, replica, and disaggregated serving choices for a workload and hardware topology.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore composable accelerators, memory fabrics, and optical inference interconnects.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Decoding acceleration and output control

Reduce generation time while preserving result quality and semantics.

Chapter operating position
Reduce generation time while preserving result quality and semantics.

6.1 Speculative decoding

Speculative decoding must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use draft models or predictors, acceptance, verification, batching, and model compatibility. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for speculative decoding.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating speculative decoding as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for speculative decoding.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Parallel candidate and tree methods

Parallel candidate and tree methods must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Generate and verify multiple tokens or branches while controlling memory and complexity. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for parallel candidate and tree methods.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating parallel candidate and tree methods as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for parallel candidate and tree methods.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Constrained decoding

Constrained decoding must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use grammars, schemas, tries, token masks, validators, retries, and repair. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for constrained decoding.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating constrained decoding as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for constrained decoding.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Early exit and adaptive compute

Early exit and adaptive compute must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Vary reasoning tokens, depth, model route, and stopping according to confidence and task. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for early exit and adaptive compute.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating early exit and adaptive compute as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for early exit and adaptive compute.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Implement a speculative-decoding simulator and measure acceptance rate, speedup, and cases where overhead dominates.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore learned draft systems and verifier-guided adaptive generation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Service reliability, observability, and autoscaling

Operate inference as a production distributed system.

Chapter operating position
Operate inference as a production distributed system.

7.1 SLOs and telemetry

SLOs and telemetry must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure queue, prefill, decode, tokens, cache, memory, batch, errors, cancellations, quality, and user latency. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for slos and telemetry.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating slos and telemetry as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for slos and telemetry.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Health and failure handling

Health and failure handling must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect model load, worker, device, memory, network, dependency, and output-validation failures. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for health and failure handling.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating health and failure handling as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for health and failure handling.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Autoscaling and capacity

Autoscaling and capacity must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Scale by queued tokens, active sequences, memory, latency, arrival rate, warmup, and model placement. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for autoscaling and capacity.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating autoscaling and capacity as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for autoscaling and capacity.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Fallback and degradation

Fallback and degradation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use smaller models, shorter context, lower output, alternate regions, cached responses, and safe rejection. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for fallback and degradation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating fallback and degradation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for fallback and degradation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory
Run a capacity exercise with traffic bursts, worker loss, memory pressure, model reload, and fallback routing.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore predictive autoscaling and self-healing model-serving fabrics.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Benchmarking, economics, and optimization governance

Optimize against representative outcomes rather than headline tokens per second.

Chapter operating position
Optimize against representative outcomes rather than headline tokens per second.

8.1 Benchmark design

Benchmark design must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control model, precision, prompt and output length, concurrency, hardware, software, warmup, and quality. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for benchmark design.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating benchmark design as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for benchmark design.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Latency and throughput reporting

Latency and throughput reporting must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Report time to first token, inter-token latency, end-to-end latency, tails, tokens, and successful requests. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for latency and throughput reporting.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
request:
  prompt_tokens: 6000
  max_output_tokens: 800
  priority: interactive
scheduler:
  continuous_batching: true
  max_running_tokens: 65536
  deadline_ms: 12000
kv_cache:
  precision: fp8
  prefix_cache: tenant-and-model-isolated
admission:
  reject_when: queued_tokens > 250000
```

Failure patterns

Treating latency and throughput reporting as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for latency and throughput reporting.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Cost and energy

Cost and energy must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure accelerator time, CPU, memory, storage, network, idle capacity, licensing, and energy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for cost and energy.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating cost and energy as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for cost and energy.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Optimization decision record

Optimization decision record must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Document evidence, quality impact, complexity, portability, regression tests, rollback, and review triggers. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the request, tokenization, admission, queue, prefill, KV state, decode, stream, completion, and service telemetry chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for optimization decision record.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating optimization decision record as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for optimization decision record.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Benchmark two serving configurations and produce a decision that includes quality, tail latency, throughput, cost, and operational risk.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore standardized agentic-inference benchmarks and energy-aware serving policy.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. vLLM Project - vLLM Documentation
Role: High-throughput LLM serving, scheduling, KV-cache, quantization, and distributed inference.
Verified: 2026-07-26
Official source: https://docs.vllm.ai/en/latest/

02. vLLM Project - Quantization
Role: Supported quantization families and deployment considerations.
Verified: 2026-07-26
Official source: https://docs.vllm.ai/en/latest/features/quantization/

03. vLLM Project - Quantized KV Cache
Role: KV-cache memory reduction and operational considerations.
Verified: 2026-07-26
Official source: https://docs.vllm.ai/en/latest/features/quantization/quantized_kvcache/

04. vLLM Project - Automatic Prefix Caching
Role: Prefix-cache architecture and reuse behavior.

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-CLD; MYTHOS-DAT; MYTHOS-SWE
Publication class	Field Guide / Canonical Living Overview Guide
Skill levels	L1 Foundational; L2 Practitioner; L3 Advanced; L4 Frontier
Tags	inference serving, vLLM, KV cache, quantization, continuous batching, speculative decoding, GPU serving, throughput, latency, autoscaling
Canonical route	/library/field-guides/mythos-fg-ai-0004/

Living publication

Corrections, expanded laboratories, improved diagrams, authority changes, and new engineering evidence should revise this permanent publication rather than create disconnected replacements.

CANONICAL LIVING OVERVIEW GUIDE

Fine-Tuning, Alignment, Synthetic Data, and Training Governance

A training and post-training guide covering objectives, datasets, SFT, PEFT, LoRA, QLoRA, preferences, DPO, reward models, synthetic data, curriculum, distributed training, evaluation, safety, provenance, release, and rollback.

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-DAT; MYTHOS-SEC; MYTHOS-SWE
Audience	Model engineers, data teams, AI researchers, evaluators, product teams, and governance leaders.
Prerequisites	Model architecture, optimization, data engineering, statistics, evaluation, and ML operations.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Choose adaptation methods according to capability gap, data, compute, risk, and deployment constraints.

Govern training data, synthetic data, labels, licenses, privacy, provenance, and contamination.

Implement SFT, LoRA-style adaptation, preference optimization, and evaluation safely.

Detect overfitting, forgetting, reward hacking, alignment tradeoffs, and distribution shift.

Release adapters or models with reproducible training records, evaluation, approval, and rollback.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Training objective and adaptation strategy

Define the capability change and select the least risky effective method.

Chapter operating position
Define the capability change and select the least risky effective method.

1.1 Capability gap and target behavior

Capability gap and target behavior must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Specify tasks, users, languages, domains, formats, safety, abstention, and failure costs. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capability gap and target behavior.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating capability gap and target behavior as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capability gap and target behavior.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Prompting, retrieval, tools, or training

Prompting, retrieval, tools, or training must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Determine whether behavior belongs in weights, context, data, tools, policy, or interface. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompting, retrieval, tools, or training.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

Treating prompting, retrieval, tools, or training as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompting, retrieval, tools, or training.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Full and parameter-efficient tuning

Full and parameter-efficient tuning must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Compare full updates, adapters, LoRA, QLoRA, prompt tuning, and selective layers. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for full and parameter-efficient tuning.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating full and parameter-efficient tuning as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for full and parameter-efficient tuning.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Success and rollback criteria

Success and rollback criteria must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define evaluation, resource, safety, compatibility, deployment, and retirement gates. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for success and rollback criteria.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating success and rollback criteria as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for success and rollback criteria.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Create an adaptation decision for a domain assistant and justify training versus retrieval, tools, and prompting.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore modular skill adapters and dynamically composed model capabilities.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Dataset design, provenance, and governance

Build training material that is lawful, representative, and traceable.

Chapter operating position
Build training material that is lawful, representative, and traceable.

2.1 Sources and licensing

Sources and licensing must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Record origin, permission, terms, ownership, consent, restrictions, and downstream obligations. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for sources and licensing.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating sources and licensing as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for sources and licensing.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Schema and examples

Schema and examples must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define instructions, inputs, context, outputs, reasoning policy, tools, metadata, and quality labels. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for schema and examples.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

Treating schema and examples as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for schema and examples.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Cleaning and deduplication

Cleaning and deduplication must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Remove corruption, secrets, personal data, duplicates, benchmark leakage, unsafe content, and low-value patterns. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for cleaning and deduplication.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating cleaning and deduplication as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for cleaning and deduplication.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Splits and versioning

Splits and versioning must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate train, validation, holdout, safety, and regression data with immutable manifests and lineage. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for splits and versioning.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating splits and versioning as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for splits and versioning.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Create a versioned training-data manifest and identify licensing, privacy, leakage, quality, and representativeness issues.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore data trusts, machine-readable consent, and cryptographically verifiable dataset lineage.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Supervised fine-tuning and PEFT

Teach desired response and task patterns efficiently.

Chapter operating position
Teach desired response and task patterns efficiently.

3.1 Tokenization and packing

Tokenization and packing must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Apply templates, labels, masking, truncation, sequence packing, loss boundaries, and special tokens. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tokenization and packing.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating tokenization and packing as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tokenization and packing.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 LoRA and low-rank adaptation

LoRA and low-rank adaptation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Select target modules, rank, scaling, dropout, initialization, merge, and adapter lifecycle. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for lora and low-rank adaptation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

Treating lora and low-rank adaptation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for lora and low-rank adaptation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Quantized fine-tuning

Quantized fine-tuning must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Combine low-bit base weights with higher-precision adapters, optimizer state, calibration, and hardware. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for quantized fine-tuning.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating quantized fine-tuning as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for quantized fine-tuning.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Training stability

Training stability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control learning rate, batch, gradient accumulation, clipping, precision, checkpointing, and validation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for training stability.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating training stability as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for training stability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory

Fine-tune a tiny PyTorch language model or adapter on a controlled dataset and inspect overfit, loss, and held-out behavior.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore adapter routing, sparse updates, and continual low-rank learning.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Preference optimization and alignment

Optimize comparative preferences without hiding evaluator assumptions.

Chapter operating position
Optimize comparative preferences without hiding evaluator assumptions.

4.1 Preference data

Preference data must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Create chosen and rejected pairs, rankings, critiques, constitutions, and uncertainty labels. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for preference data.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating preference data as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for preference data.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Reward models and feedback

Reward models and feedback must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Train and validate preference models, detect shortcuts, disagreement, distribution shift, and reward hacking. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for reward models and feedback.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

- Treating reward models and feedback as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for reward models and feedback.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 DPO and related objectives

DPO and related objectives must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Understand reference policy, preference likelihood, regularization, beta, and optimization behavior. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for dpo and related objectives.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating dpo and related objectives as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for dpo and related objectives.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Safety and capability tradeoffs

Safety and capability tradeoffs must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure refusal, helpfulness, truthfulness, calibration, style, and task performance by slice. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for safety and capability tradeoffs.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating safety and capability tradeoffs as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for safety and capability tradeoffs.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Build a small preference dataset and compare rule-based ranking, reward scoring, and DPO-style objectives conceptually or experimentally.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore pluralistic alignment and personalized policies with explicit user control.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Synthetic data and curriculum engineering

Generate useful data without amplifying model errors and artifacts.

Chapter operating position
Generate useful data without amplifying model errors and artifacts.

5.1 Generation pipelines

Generation pipelines must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use seed tasks, templates, models, tools, simulators, retrieval, and self-play to create examples. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for generation pipelines.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating generation pipelines as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for generation pipelines.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Filtering and verification

Filtering and verification must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Apply schemas, deterministic checks, execution, experts, judges, diversity, novelty, and confidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for filtering and verification.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

Treating filtering and verification as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for filtering and verification.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Curriculum and difficulty

Curriculum and difficulty must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Sequence concepts, task complexity, counterexamples, rare cases, and recovery behavior. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for curriculum and difficulty.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating curriculum and difficulty as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for curriculum and difficulty.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Feedback loops and contamination

Feedback loops and contamination must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Prevent self-reinforcing errors, benchmark leakage, homogenization, synthetic signatures, and hidden provenance. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for feedback loops and contamination.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating feedback loops and contamination as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for feedback loops and contamination.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory
Generate a synthetic training set with deterministic validation and measure diversity, error rate, leakage, and marginal value.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore simulator-generated trajectories and adversarial co-evolution of data and models.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Training systems, efficiency, and checkpoints

Operate training as a reliable distributed computation.

Chapter operating position
Operate training as a reliable distributed computation.

6.1 Data and model parallelism

Data and model parallelism must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Partition batches, parameters, gradients, optimizer state, experts, and pipeline stages. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for data and model parallelism.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating data and model parallelism as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for data and model parallelism.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Memory and precision

Memory and precision must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use mixed precision, checkpointing, offload, sharding, accumulation, and sequence packing. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for memory and precision.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

Treating memory and precision as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for memory and precision.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Checkpoint and resume

Checkpoint and resume must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Record model, optimizer, scheduler, scaler, RNG, data position, code, config, and hardware state. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for checkpoint and resume.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating checkpoint and resume as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for checkpoint and resume.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Failure and cost control

Failure and cost control must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle worker loss, NaNs, divergence, data errors, quota, preemption, and budget. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for failure and cost control.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating failure and cost control as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for failure and cost control.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Run a tiny training job with checkpoint, interruption, deterministic resume, and artifact comparison.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore elastic training, distributed checkpoint fabrics, and energy-aware scheduling.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Evaluation, safety, and release qualification

Prove that adaptation improved the intended behavior without unacceptable regression.

Chapter operating position
Prove that adaptation improved the intended behavior without unacceptable regression.

7.1 Capability and slice evaluation

Capability and slice evaluation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure target task, general capability, languages, formats, domains, and user populations. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capability and slice evaluation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating capability and slice evaluation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capability and slice evaluation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Safety and robustness

Safety and robustness must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test harmful use, prompt injection, privacy, memorization, refusal, over-compliance, and distribution shift. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for safety and robustness.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

Treating safety and robustness as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for safety and robustness.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Base versus tuned comparison

Base versus tuned comparison must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use paired outputs, blinded review, deterministic tests, significance, and critical regressions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for base versus tuned comparison.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating base versus tuned comparison as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for base versus tuned comparison.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Model card and release evidence

Model card and release evidence must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Publish data, method, hyperparameters, compute, evaluation, limitations, license, risks, and intended use. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for model card and release evidence.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating model card and release evidence as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for model card and release evidence.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory
Create a release report comparing base and tuned models with critical-failure gates and rollback criteria.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore continuous post-training evaluation and automatically generated assurance cases.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Lifecycle, governance, and continual adaptation

Control adapters and model variants after deployment.

Chapter operating position
Control adapters and model variants after deployment.

8.1 Variant registry

Variant registry must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Track base, adapter, tokenizer, template, data, code, evaluation, compatibility, owner, and status. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for variant registry.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating variant registry as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for variant registry.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Monitoring and drift

Monitoring and drift must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Observe task quality, user feedback, safety, data change, tools, retrieval, latency, and incidents. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for monitoring and drift.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
training_run:
  base_model_digest: sha256:...
  dataset_manifest: data/v3/manifest.json
  method: lora
  targets: [q_proj, v_proj]
  seed: 42
  checkpoints:
    include: [model, optimizer, scheduler, rng, data_position]
  release_gates:
    - target-task-improved
    - safety-regression-zero
    - heldout-contamination-check-pass
```

Failure patterns

- Treating monitoring and drift as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for monitoring and drift.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Update and rollback

Update and rollback must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use staged rollout, canaries, A/B tests, adapter switch, model fallback, and retained prior artifacts. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for update and rollback.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating update and rollback as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for update and rollback.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Retirement and data obligations

Retirement and data obligations must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Remove unsupported variants, revoke access, archive evidence, respect deletion, and update downstream users. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the objective, dataset, tokenizer, model, optimizer, checkpoint, evaluation, release, deployment, and monitoring chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for retirement and data obligations.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating retirement and data obligations as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for retirement and data obligations.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Design a registry and rollout process for multiple adapters sharing one base model across teams.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore online adaptation with bounded memory, user-specific adapters, and verifiable unlearning.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-UX; MYTHOS-SWE; MYTHOS-EMT
Audience	AI, vision, speech, realtime, desktop, mobile, robotics, accessibility, and product engineers.
Prerequisites	Model architecture, signal processing basics, networking, UI engineering, privacy, and evaluation.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Design multimodal pipelines from capture and preprocessing through model fusion and output.

Engineer realtime voice and vision interactions with bounded latency, interruption, and recovery.

Ground model outputs to image regions, document structure, time, speaker, and sensor state.

Protect biometric, visual, audio, environmental, and accessibility-sensitive data.

Evaluate multimodal quality, safety, synchronization, latency, and user outcomes.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Multimodal system architecture

Define modality boundaries, timing, representations, and fusion.

Chapter operating position
Define modality boundaries, timing, representations, and fusion.

1.1 Capture and ingestion

Capture and ingestion must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Acquire images, documents, audio, video, screens, sensors, metadata, consent, and device state. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capture and ingestion.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating capture and ingestion as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capture and ingestion.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Preprocessing and segmentation

Preprocessing and segmentation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Resize, crop, normalize, denoise, sample, segment, detect speech, and preserve coordinates or timestamps. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for preprocessing and segmentation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating preprocessing and segmentation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for preprocessing and segmentation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Modality encoders and tokens

Modality encoders and tokens must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Represent patches, regions, frames, spectrograms, waveforms, speakers, and actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for modality encoders and tokens.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating modality encoders and tokens as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for modality encoders and tokens.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Fusion and generation

Fusion and generation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use shared spaces, cross-attention, adapters, late fusion, tool calls, and modality-specific decoders. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for fusion and generation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating fusion and generation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for fusion and generation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Build a multimodal pipeline specification that preserves coordinate, timestamp, speaker, and provenance information.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore unified realtime world models and modality-agnostic token streams.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Vision and document intelligence

Interpret natural images, screens, diagrams, and structured documents.

Chapter operating position
Interpret natural images, screens, diagrams, and structured documents.

2.1 Image understanding

Image understanding must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle objects, attributes, relationships, scenes, text, charts, spatial layout, and uncertainty. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for image understanding.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating image understanding as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for image understanding.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Document structure

Document structure must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Preserve pages, blocks, tables, reading order, forms, captions, footnotes, and citations. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for document structure.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating document structure as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for document structure.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Grounding and localization

Grounding and localization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Return regions, boxes, masks, page references, confidence, and evidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for grounding and localization.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating grounding and localization as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for grounding and localization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Visual action and UI understanding

Visual action and UI understanding must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Interpret interfaces, state, affordances, accessibility tree, screenshots, and safe actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for visual action and ui understanding.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating visual action and ui understanding as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for visual action and ui understanding.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Evaluate a vision system on charts, forms, interfaces, and ambiguous images with region-level evidence.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore spatial reasoning, 3D scene understanding, and embodied visual planning.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Audio, speech recognition, and speaker context

Convert acoustic streams into reliable, contextual interaction.

Chapter operating position
Convert acoustic streams into reliable, contextual interaction.

3.1 Audio capture and preprocessing

Audio capture and preprocessing must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Manage sample rate, channels, gain, echo, noise, clipping, devices, buffers, and permissions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for audio capture and preprocessing.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating audio capture and preprocessing as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for audio capture and preprocessing.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 Speech recognition

Speech recognition must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use acoustic and language models, token timing, punctuation, confidence, partial transcripts, and domain vocabulary. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for speech recognition.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating speech recognition as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for speech recognition.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Speaker and diarization context

Speaker and diarization context must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate speakers, turns, overlap, identity claims, privacy, and uncertainty. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for speaker and diarization context.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating speaker and diarization context as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for speaker and diarization context.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Non-speech audio

Non-speech audio must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect alarms, environment, music, emotion cues, and events without overinterpreting. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for non-speech audio.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating non-speech audio as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for non-speech audio.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Build a streaming transcription pipeline with partial results, timestamps, cancellation, vocabulary hints, and error analysis.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore source separation, neural codecs, and privacy-preserving acoustic understanding.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Speech synthesis, voice, and presence

Generate understandable, controllable audio without deceptive identity or unsafe behavior.

Chapter operating position
Generate understandable, controllable audio without deceptive identity or unsafe behavior.

4.1 Text normalization and prosody

Text normalization and prosody must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle numbers, abbreviations, pronunciation, pauses, emphasis, emotion, and markup. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for text normalization and prosody.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating text normalization and prosody as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for text normalization and prosody.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Streaming synthesis

Streaming synthesis must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Generate and play chunks, control buffering, cancellation, interruption, and device changes. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for streaming synthesis.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating streaming synthesis as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for streaming synthesis.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Voice identity and consent

Voice identity and consent must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Govern voice selection, cloning, disclosure, watermarking, impersonation, and revocation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for voice identity and consent.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating voice identity and consent as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for voice identity and consent.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Accessibility and personalization

Accessibility and personalization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Support speed, pitch, captions, transcripts, alternate modalities, and user preferences. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for accessibility and personalization.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating accessibility and personalization as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for accessibility and personalization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Design a TTS session with interruption, pronunciation controls, disclosure, captions, and fallback text.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore expressive controllable speech and locally generated personalized voices with consent.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Realtime transport and conversational turn-taking

Maintain natural interaction under network, model, and user variability.

Chapter operating position
Maintain natural interaction under network, model, and user variability.

5.1 Streaming transport

Streaming transport must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use WebRTC or streaming protocols, encryption, congestion control, jitter buffers, reconnect, and media state. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for streaming transport.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating streaming transport as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for streaming transport.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Voice activity and endpointing

Voice activity and endpointing must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect speech start, end, silence, overlap, background noise, push-to-talk, and user override. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for voice activity and endpointing.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating voice activity and endpointing as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for voice activity and endpointing.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Barge-in and interruption

Barge-in and interruption must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Cancel synthesis, stop generation, preserve context, distinguish corrections, and resume safely. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for barge-in and interruption.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating barge-in and interruption as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for barge-in and interruption.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Latency budget

Latency budget must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure capture, transport, recognition, reasoning, tools, synthesis, playback, and user-perceived response. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for latency budget.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating latency budget as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for latency budget.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory
Create a realtime session simulator with VAD, partial transcripts, barge-in, tool delay, reconnect, and latency telemetry.

Laboratory evidence package

Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.

Versioned configuration or code with explanatory comments and reproducible setup instructions.

Nominal-path validation plus at least two injected failure or boundary conditions.

Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.

A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore predictive turn-taking and full-duplex conversational models.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Video, temporal reasoning, and sensor fusion

Understand events and state across time rather than independent frames.

Chapter operating position
Understand events and state across time rather than independent frames.

6.1 Sampling and representation

Sampling and representation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Choose frame rate, clips, keyframes, tracks, motion, audio, captions, and memory. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for sampling and representation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating sampling and representation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for sampling and representation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Temporal events and causality

Temporal events and causality must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Identify order, duration, repetition, change, actors, goals, and uncertain causes. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for temporal events and causality.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating temporal events and causality as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for temporal events and causality.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Long-video retrieval

Long-video retrieval must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Index segments, transcripts, objects, scenes, summaries, events, and citations. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for long-video retrieval.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating long-video retrieval as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for long-video retrieval.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Sensor and action fusion

Sensor and action fusion must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Combine video, audio, location, telemetry, control, and environment state. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for sensor and action fusion.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating sensor and action fusion as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for sensor and action fusion.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Build a video event index and answer questions with exact time ranges and evidence.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore long-horizon video memory and predictive world simulation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Safety, privacy, accessibility, and misuse

Protect people and environments represented by rich sensor data.

Chapter operating position
Protect people and environments represented by rich sensor data.

7.1 Sensitive and biometric data

Sensitive and biometric data must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle faces, voices, locations, screens, documents, health, children, bystanders, and consent. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for sensitive and biometric data.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating sensitive and biometric data as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for sensitive and biometric data.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Prompt injection and visual attacks

Prompt injection and visual attacks must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test hidden text, adversarial images, QR codes, UI content, audio injection, and cross-modal instructions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompt injection and visual attacks.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating prompt injection and visual attacks as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompt injection and visual attacks.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Misidentification and uncertainty

Misidentification and uncertainty must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Avoid unsupported identity, intent, emotion, medical, legal, or safety conclusions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for misidentification and uncertainty.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating misidentification and uncertainty as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for misidentification and uncertainty.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Accessible multimodal design

Accessible multimodal design must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Provide captions, transcripts, keyboard paths, focus, contrast, descriptions, and user control. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for accessible multimodal design.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating accessible multimodal design as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for accessible multimodal design.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory

Threat-model a camera and voice assistant and test indirect prompt injection, bystander privacy, and accessibility failure.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore on-device redaction and privacy-preserving multimodal inference.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Multimodal evaluation and operations

Measure quality and system behavior across modalities and timing.

Chapter operating position
Measure quality and system behavior across modalities and timing.

8.1 Task and slice design

Task and slice design must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate languages, accents, devices, lighting, noise, documents, users, accessibility, and adversarial inputs. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for task and slice design.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating task and slice design as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for task and slice design.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Grounding and synchronization metrics

Grounding and synchronization metrics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure region, time, speaker, transcription, retrieval, factuality, and cross-modal consistency. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for grounding and synchronization metrics.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
realtime_session:
  transport: webrtc
  audio:
    sample_rate_hz: 24000
    vad: server-with-user-override
  interaction:
    partial_transcripts: true
    barge_in: cancel-generation-and-playback
  privacy:
    raw_media_retention: none
  metrics:
    - speech_start_to_partial_ms
    - end_of_turn_to_first_audio_ms
    - interruption_stop_ms
```

Failure patterns

- Treating grounding and synchronization metrics as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for grounding and synchronization metrics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Realtime service metrics

Realtime service metrics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure endpointing, interruption, latency, jitter, dropped media, reconnection, resource use, and user outcome. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for realtime service metrics.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating realtime service metrics as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for realtime service metrics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Monitoring and lifecycle

Monitoring and lifecycle must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Track model, codec, device, browser, runtime, permissions, drift, incidents, updates, and rollback. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the capture, preprocessing, representation, fusion, model state, grounding, realtime transport, output, and user response chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for monitoring and lifecycle.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating monitoring and lifecycle as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for monitoring and lifecycle.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Build a multimodal evaluation suite covering vision grounding, transcription, turn-taking, safety, accessibility, and latency.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore standardized realtime multimodal benchmarks and human-centered quality models.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-UX; MYTHOS-SWE; MYTHOS-EMT
Publication class	Field Guide / Canonical Living Overview Guide
Skill levels	L1 Foundational; L2 Practitioner; L3 Advanced; L4 Frontier

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-DAT; MYTHOS-SWE; MYTHOS-SEC
Audience	AI application, agent, memory, retrieval, platform, and developer-tool engineers.
Prerequisites	Transformers, tokenization, prompting, retrieval, software architecture, and evaluation.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Allocate context among instructions, task state, repository data, retrieval, tools, memory, and output.

Select and order evidence according to relevance, authority, freshness, dependency, and position.

Compact long trajectories without losing commitments, unresolved work, provenance, or recovery state.

Measure token, cache, latency, quality, and context-loss tradeoffs.

Protect context from injection, cross-tenant leakage, secret exposure, and untrusted summaries.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Context architecture and token accounting

Treat the context window as a scarce, typed working memory.

Chapter operating position
Treat the context window as a scarce, typed working memory.

1.1 Tokenizer behavior

Tokenizer behavior must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Understand tokens, bytes, Unicode, code, tables, images, special tokens, and model-specific differences. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tokenizer behavior.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating tokenizer behavior as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tokenizer behavior.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Budget partitions

Budget partitions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Allocate system policy, user task, state, retrieval, memory, tools, examples, reasoning allowance, and output. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for budget partitions.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

Treating budget partitions as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for budget partitions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Hard and soft limits

Hard and soft limits must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle maximum context, reserved output, provider limits, tool schemas, multimodal tokens, and safety margins. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for hard and soft limits.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating hard and soft limits as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for hard and soft limits.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Cost and latency

Cost and latency must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Relate input tokens, cache hits, prefill, throughput, provider cost, memory, and user delay. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for cost and latency.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating cost and latency as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for cost and latency.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Build a token budgeter that rejects, truncates, retrieves, or compacts according to typed context classes.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore semantic token allocation and adaptive model-specific budgets.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Instruction hierarchy and prompt structure

Separate authority, task, data, examples, and untrusted content.

Chapter operating position
Separate authority, task, data, examples, and untrusted content.

2.1 System and policy instructions

System and policy instructions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define identity, authority, constraints, tool rules, output contract, and conflict handling. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for system and policy instructions.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating system and policy instructions as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for system and policy instructions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Task and acceptance context

Task and acceptance context must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Provide objective, scope, dependencies, state, artifacts, tests, and completion evidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for task and acceptance context.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

- Treating task and acceptance context as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for task and acceptance context.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Examples and demonstrations

Examples and demonstrations must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Choose representative, diverse, non-leaking examples with clear boundaries and labels. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for examples and demonstrations.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating examples and demonstrations as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for examples and demonstrations.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Data and untrusted content

Data and untrusted content must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Mark documents, tool outputs, web content, code comments, messages, and retrieved text as data rather than authority. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for data and untrusted content.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating data and untrusted content as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for data and untrusted content.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory

Create a prompt layout resistant to indirect instructions embedded in retrieved documents and repository files.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore typed prompt languages and cryptographically labeled instruction provenance.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Selection, relevance, authority, and freshness

Choose the smallest context that preserves the decision-relevant system state.

Chapter operating position
Choose the smallest context that preserves the decision-relevant system state.

3.1 Relevance and dependency

Relevance and dependency must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Rank direct task evidence, interfaces, callers, state, tests, related incidents, and neighboring modules. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for relevance and dependency.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating relevance and dependency as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for relevance and dependency.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 Authority and source tiers

Authority and source tiers must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Prefer normative specifications, current source of truth, approved policy, primary evidence, and explicit user decisions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for authority and source tiers.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

- Treating authority and source tiers as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for authority and source tiers.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Freshness and change detection

Freshness and change detection must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Track versions, timestamps, commits, schema, model, policy, index, and invalidation triggers. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for freshness and change detection.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating freshness and change detection as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for freshness and change detection.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Diversity and contradiction

Diversity and contradiction must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Include competing evidence, unresolved conflicts, uncertainty, and minority failure cases when decision-relevant. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for diversity and contradiction.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating diversity and contradiction as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for diversity and contradiction.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Score a candidate context set and remove low-value material while preserving all authoritative dependencies and contradictions.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore learned context selection constrained by source authority.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Long-context behavior and position effects

Use large windows without assuming uniform attention or recall.

Chapter operating position
Use large windows without assuming uniform attention or recall.

4.1 Position sensitivity

Position sensitivity must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test beginning, middle, end, recency, ordering, separators, and repeated instructions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for position sensitivity.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating position sensitivity as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for position sensitivity.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Distractors and overload

Distractors and overload must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure irrelevant documents, duplicated text, similar identifiers, conflicting versions, and noisy examples. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for distractors and overload.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

Treating distractors and overload as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for distractors and overload.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Hierarchical organization

Hierarchical organization must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use maps, summaries, indexes, sections, citations, and progressive disclosure. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for hierarchical organization.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating hierarchical organization as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for hierarchical organization.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Long-context evaluation

Long-context evaluation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Create needle, multi-hop, synthesis, chronology, codebase, and state-consistency tests. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for long-context evaluation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating long-context evaluation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for long-context evaluation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Run a lost-in-the-middle experiment with controlled evidence positions and distractor density.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore recurrent memory, infinite-context approximations, and external attention stores.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Caching, reuse, and stable prefixes

Reuse expensive context without serving stale or cross-tenant state.

Chapter operating position
Reuse expensive context without serving stale or cross-tenant state.

5.1 Prompt and prefix caching

Prompt and prefix caching must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Identify stable instructions, schemas, repositories, documents, and repeated conversation prefixes. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompt and prefix caching.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating prompt and prefix caching as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompt and prefix caching.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Cache identity and isolation

Cache identity and isolation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Key by model, tokenizer, template, policy, tenant, data version, adapter, and tool schema. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for cache identity and isolation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

- Treating cache identity and isolation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for cache identity and isolation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Invalidation and freshness

Invalidation and freshness must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Expire or rebuild on policy, source, permission, model, index, or user-state change. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for invalidation and freshness.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating invalidation and freshness as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for invalidation and freshness.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Quality and economics

Quality and economics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure prefill avoided, latency, memory, hit rate, fragmentation, leakage risk, and stale results. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for quality and economics.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating quality and economics as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for quality and economics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory
Design a cache key and invalidation strategy for multi-tenant repository agents.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore distributed semantic caches with verifiable privacy boundaries.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Summarization and trajectory compaction

Compress interaction history while preserving executable state and evidence.

Chapter operating position
Compress interaction history while preserving executable state and evidence.

6.1 Conversation and task summaries

Conversation and task summaries must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Preserve objective, decisions, constraints, artifacts, results, unresolved issues, and next actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for conversation and task summaries.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating conversation and task summaries as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for conversation and task summaries.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Tool trajectory records

Tool trajectory records must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Store action, arguments, observation, state change, evidence, error, retry, and compensation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tool trajectory records.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

- Treating tool trajectory records as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tool trajectory records.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Loss and hallucination controls

Loss and hallucination controls must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use source-linked summaries, deterministic extraction, validation, confidence, and retained raw records. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for loss and hallucination controls.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating loss and hallucination controls as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for loss and hallucination controls.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Checkpoint and restore

Checkpoint and restore must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Create compact state snapshots that allow another model or agent to resume and verify work. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for checkpoint and restore.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating checkpoint and restore as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for checkpoint and restore.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Compact a long agent trajectory into a resume package and test whether another agent can continue without repeating or violating decisions.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore learned trajectory compression and event-sourced agent memory.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Multi-agent and multi-model context fabric

Share necessary state without flooding every agent or leaking authority.

Chapter operating position
Share necessary state without flooding every agent or leaking authority.

7.1 Private and shared context

Private and shared context must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate agent scratch, task state, evidence, decisions, common memory, and restricted data. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for private and shared context.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating private and shared context as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for private and shared context.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Role-specific views

Role-specific views must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Give planners, implementers, reviewers, testers, and supervisors different context projections. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for role-specific views.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

- Treating role-specific views as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for role-specific views.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Handoffs and fan-in

Handoffs and fan-in must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use typed deliverables, claims, citations, conflicts, confidence, and unresolved dependencies. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for handoffs and fan-in.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating handoffs and fan-in as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for handoffs and fan-in.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Consistency and concurrency

Consistency and concurrency must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle simultaneous edits, stale plans, duplicated work, conflicting summaries, and supervisor reconciliation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for consistency and concurrency.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating consistency and concurrency as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for consistency and concurrency.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory
Run three role-specific agents on one task using separate context views and a governed reconciliation record.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore distributed context services with transactional state and semantic access control.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Security, evaluation, and operations

Treat context as a high-value execution and information-security boundary.

Chapter operating position
Treat context as a high-value execution and information-security boundary.

8.1 Prompt injection and authority confusion

Prompt injection and authority confusion must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test direct, indirect, retrieved, tool, memory, image, and repository instructions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompt injection and authority confusion.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating prompt injection and authority confusion as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompt injection and authority confusion.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Secrets and cross-tenant isolation

Secrets and cross-tenant isolation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Prevent credentials, private data, hidden prompts, embeddings, cache entries, and logs from crossing boundaries. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for secrets and cross-tenant isolation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
context_budget:
  total_tokens: 65536
  reserve_output: 8192
  partitions:
    system_policy: 4000
    task_state: 8000
    repository_map: 10000
    retrieved_evidence: 24000
    trajectory_summary: 6000
  overflow_policy:
    - remove_low_authority
    - deduplicate
    - retrieve_on_demand
    - compact_with_citations
```

Failure patterns

- Treating secrets and cross-tenant isolation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for secrets and cross-tenant isolation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Context quality metrics

Context quality metrics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure relevance, authority, freshness, coverage, contradiction, token efficiency, cache reuse, and task outcome. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for context quality metrics.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating context quality metrics as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for context quality metrics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Lifecycle and incident response

Lifecycle and incident response must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Trace context versions, delete data, invalidate caches, inspect leaks, restore safe state, and update policy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the authority, instruction, selected evidence, token budget, working state, cache, compaction, handoff, and task outcome chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for lifecycle and incident response.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating lifecycle and incident response as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for lifecycle and incident response.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory

Red-team a context pipeline for injection, stale source, summary corruption, cache leakage, and missing critical evidence.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop a source-authority-aware context operating system with continuous evaluation.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. Stanford University - Lost in the Middle
Role: Long-context position sensitivity evaluation.
Verified: 2026-07-26
Official source: https://arxiv.org/abs/2307.03172

02. Google Brain / CMU - Transformer-XL
Role: Segment-level recurrence and long-context modeling.
Verified: 2026-07-26
Official source: https://arxiv.org/abs/1901.02860

03. UC Berkeley - MemGPT: Towards LLMs as Operating Systems
Role: Tiered memory and context-management architecture.
Verified: 2026-07-26
Official source: https://arxiv.org/abs/2310.08560

04. vLLM Project - Automatic Prefix Caching
Role: Prefix-cache architecture and reuse behavior.
Verified: 2026-07-26
Official source: https://docs.vllm.ai/en/stable/design/prefix_caching/

05. Model Context Protocol - Model Context Protocol Specification 2025-11-25
Role: Authoritative protocol requirements for resources, prompts, tools, transports, authorization, and lifecycle.
Verified: 2026-07-26
Official source: https://modelcontextprotocol.io/specification/2025-11-25

06. NIST - NIST AI 600-1 - Generative Artificial Intelligence Profile
Role: Generative-AI risk profile and recommended actions.
Verified: 2026-07-26
Official source: https://nvlpubs.nist.gov/nistpubs/ai/NIST.AI.600-1.pdf

07. OWASP GenAI Security Project - OWASP Top 10 for LLM and GenAI Applications 2025
Role: Risk and mitigation baseline for generative-AI applications.
Verified: 2026-07-26
Official source: https://genai.owasp.org/llm-top-10/

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Dimension	Engineering position

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-DAT; MYTHOS-SEC; MYTHOS-SWE
Audience	RAG, knowledge, search, memory, agent, data, security, and AI application engineers.
Prerequisites	Information retrieval, databases, AI models, data governance, APIs, and evaluation.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Build knowledge pipelines that preserve identity, structure, source authority, access, and freshness.

Combine lexical, dense, metadata, graph, and reranking methods according to task.

Generate answers with traceable evidence, citation validation, uncertainty, and conflict disclosure.

Design working, episodic, semantic, procedural, and user memory with explicit retention and authority.

Evaluate retrieval, grounding, citation, memory, security, and end-to-end task outcomes.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Knowledge architecture and source authority

Define which sources may support which claims and decisions.

Chapter operating position
Define which sources may support which claims and decisions.

1.1 Source classes and authority

Source classes and authority must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Distinguish normative, primary, internal authoritative, operational evidence, expert, secondary, and unverified sources. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for source classes and authority.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating source classes and authority as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for source classes and authority.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Identity and lineage

Identity and lineage must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Assign stable IDs, versions, owners, origin, transformations, permissions, hashes, and supersession. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for identity and lineage.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating identity and lineage as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for identity and lineage.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Freshness and validity

Freshness and validity must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Track publication, verification, effective, expiry, review, change triggers, and conflicting versions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for freshness and validity.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating freshness and validity as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for freshness and validity.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Claim and use restrictions

Claim and use restrictions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Limit source use by domain, user, tenant, geography, license, confidentiality, and decision risk. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for claim and use restrictions.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating claim and use restrictions as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for claim and use restrictions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory

Create a source-authority policy and resolve a conflict among a standard, vendor guide, internal runbook, and stale incident note.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore cryptographically verifiable knowledge lineage and automated authority scoring.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Ingestion, parsing, and canonical representation

Convert heterogeneous sources without losing structure and provenance.

Chapter operating position
Convert heterogeneous sources without losing structure and provenance.

2.1 Connectors and acquisition

Connectors and acquisition must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Retrieve files, repositories, databases, APIs, messages, tickets, pages, media, and structured records. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for connectors and acquisition.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating connectors and acquisition as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for connectors and acquisition.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Parsing and structure

Parsing and structure must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Preserve documents, sections, tables, code, diagrams, pages, fields, timestamps, and relationships. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for parsing and structure.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating parsing and structure as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for parsing and structure.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Normalization and enrichment

Normalization and enrichment must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Add canonical IDs, entities, language, permissions, topics, embeddings, links, and quality metadata. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for normalization and enrichment.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating normalization and enrichment as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for normalization and enrichment.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Change capture and deletion

Change capture and deletion must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect additions, modifications, moves, supersession, revocation, retention, and source removal. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for change capture and deletion.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating change capture and deletion as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for change capture and deletion.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Ingest a mixed corpus and prove every normalized segment can be traced to its original source and access policy.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore multimodal semantic parsing and continuously reconciled knowledge twins.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Chunking, embeddings, and indexes

Create retrieval units aligned to meaning, tasks, and source structure.

Chapter operating position
Create retrieval units aligned to meaning, tasks, and source structure.

3.1 Chunk boundaries

Chunk boundaries must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use semantic, structural, sliding, code-aware, table-aware, and hierarchical segmentation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for chunk boundaries.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating chunk boundaries as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for chunk boundaries.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 Embedding models and spaces

Embedding models and spaces must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Select model, dimension, language, domain, normalization, version, and privacy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for embedding models and spaces.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating embedding models and spaces as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for embedding models and spaces.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Lexical and vector indexes

Lexical and vector indexes must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use inverted indexes, ANN structures, metadata filters, namespaces, updates, and tombstones. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for lexical and vector indexes.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating lexical and vector indexes as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for lexical and vector indexes.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Index quality and drift

Index quality and drift must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure coverage, duplicates, orphan chunks, embedding changes, source mismatch, and stale entries. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for index quality and drift.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating index quality and drift as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for index quality and drift.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Compare fixed, structural, and semantic chunking on a technical corpus using retrieval and citation outcomes.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore late-interaction retrieval and learned task-specific indexes.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Retrieval, reranking, and graph reasoning

Find evidence through complementary retrieval strategies.

Chapter operating position
Find evidence through complementary retrieval strategies.

4.1 Query understanding

Query understanding must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Extract intent, entities, constraints, time, authority, permissions, subquestions, and expected evidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for query understanding.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating query understanding as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for query understanding.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 Hybrid retrieval

Hybrid retrieval must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Combine keyword, dense, metadata, recency, authority, popularity, and exact identifiers. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for hybrid retrieval.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating hybrid retrieval as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for hybrid retrieval.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Reranking and diversity

Reranking and diversity must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use cross-encoders or judges, relevance, authority, freshness, novelty, redundancy, and coverage. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for reranking and diversity.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating reranking and diversity as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for reranking and diversity.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 Graph and multi-hop retrieval

Graph and multi-hop retrieval must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Traverse entities, documents, communities, dependencies, citations, and temporal relationships. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for graph and multi-hop retrieval.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating graph and multi-hop retrieval as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for graph and multi-hop retrieval.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Build a hybrid retrieval pipeline and compare dense-only, lexical-only, reranked, and graph-assisted results.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore agentic retrieval planning and causal knowledge graphs.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Grounded generation and citation engineering

Ensure outputs remain linked to evidence and disclose unsupported claims.

Chapter operating position
Ensure outputs remain linked to evidence and disclose unsupported claims.

5.1 Evidence packaging

Evidence packaging must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Provide source text, metadata, authority, date, permissions, section, page, and stable citation ID. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for evidence packaging.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating evidence packaging as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for evidence packaging.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Answer construction

Answer construction must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate sourced facts, calculations, inference, uncertainty, conflicts, and recommendations. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for answer construction.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating answer construction as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for answer construction.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Citation validation

Citation validation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Verify cited text supports the claim, source exists, permissions allow use, and locations are stable. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for citation validation.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating citation validation as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for citation validation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Insufficient evidence and abstention

Insufficient evidence and abstention must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Ask for data, narrow the claim, present alternatives, or decline unsupported certainty. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for insufficient evidence and abstention.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating insufficient evidence and abstention as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for insufficient evidence and abstention.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory
Generate answers over a conflicting corpus and score claim-level support, authority, freshness, and citation correctness.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore proof-producing generation and machine-checkable claim graphs.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Memory models and lifecycle

Store durable state without confusing memory, knowledge, conversation, and authority.

Chapter operating position
Store durable state without confusing memory, knowledge, conversation, and authority.

6.1 Working and short-term memory

Working and short-term memory must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Maintain active goals, variables, constraints, intermediate results, and recent interaction. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for working and short-term memory.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating working and short-term memory as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for working and short-term memory.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Episodic and trajectory memory

Episodic and trajectory memory must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Store events, tasks, actions, observations, outcomes, errors, and lessons with timestamps. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for episodic and trajectory memory.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating episodic and trajectory memory as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for episodic and trajectory memory.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 Semantic and procedural memory

Semantic and procedural memory must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Represent stable facts, preferences, concepts, policies, workflows, and skill knowledge. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for semantic and procedural memory.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating semantic and procedural memory as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for semantic and procedural memory.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Retention, consent, and forgetting

Retention, consent, and forgetting must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control user choice, purpose, access, expiry, correction, deletion, and derived artifacts. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for retention, consent, and forgetting.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating retention, consent, and forgetting as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for retention, consent, and forgetting.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Design a memory schema and demonstrate promotion, correction, expiry, deletion, and cross-session retrieval.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore personal semantic memory with user-owned encrypted stores and verifiable forgetting.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Security, privacy, and multi-tenant isolation

Prevent knowledge systems from becoming exfiltration and authority-confusion channels.

Chapter operating position
Prevent knowledge systems from becoming exfiltration and authority-confusion channels.

7.1 Access-aware retrieval

Access-aware retrieval must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Apply user, role, tenant, document, field, purpose, and row-level permissions before ranking. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for access-aware retrieval.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating access-aware retrieval as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for access-aware retrieval.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Indirect prompt injection

Indirect prompt injection must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Treat documents, pages, messages, code, images, and tool outputs as untrusted data. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for indirect prompt injection.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating indirect prompt injection as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for indirect prompt injection.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Sensitive data and embeddings

Sensitive data and embeddings must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Control secrets, personal data, model inversion risk, logs, caches, backups, and index exports. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for sensitive data and embeddings.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating sensitive data and embeddings as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for sensitive data and embeddings.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Poisoning and integrity

Poisoning and integrity must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect malicious sources, modified content, fake authority, link manipulation, and embedding attacks. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for poisoning and integrity.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating poisoning and integrity as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for poisoning and integrity.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory

Red-team a multi-tenant RAG system for cross-tenant retrieval, injection, poisoned sources, stale permissions, and citation spoofing.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore encrypted retrieval, confidential vector search, and signed source assertions.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Evaluation, observability, and lifecycle operations

Measure the complete knowledge-to-answer pipeline and keep it current.

Chapter operating position
Measure the complete knowledge-to-answer pipeline and keep it current.

8.1 Retrieval metrics

Retrieval metrics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure recall, precision, ranking, nDCG, authority, freshness, diversity, and permission correctness. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for retrieval metrics.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating retrieval metrics as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for retrieval metrics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Grounding and answer metrics

Grounding and answer metrics must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure claim support, citation precision, contradiction, completeness, abstention, and user outcome. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for grounding and answer metrics.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
claim:
  text: "The active policy requires phishing-resistant authentication."
  support:
    source_id: POLICY-IAM-004
    version: 7
    location: section-3.2
    authority: internal-normative
    verified_at: 2026-07-26
  inference: false
  citation_validated: true
  conflict_state: none
```

Failure patterns

- Treating grounding and answer metrics as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for grounding and answer metrics.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Pipeline observability

Pipeline observability must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Trace query, filters, candidates, scores, reranking, context, generation, citations, cache, and latency. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for pipeline observability.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating pipeline observability as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for pipeline observability.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Reindex, migration, and incident response

Reindex, migration, and incident response must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle source changes, embedding upgrades, corrupt indexes, leaks, model changes, rollback, and evidence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the source, lineage, parsing, chunk, index, retrieval, rerank, grounded claim, citation, memory, and lifecycle chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for reindex, migration, and incident response.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating reindex, migration, and incident response as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for reindex, migration, and incident response.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory
Create an end-to-end RAG evaluation set and operational dashboard with failure slices and reindex rollback.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop self-auditing knowledge systems that continuously verify authority and citation integrity.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. Meta AI Research - Retrieval-Augmented Generation for Knowledge-Intensive NLP Tasks

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-DAT; MYTHOS-SEC; MYTHOS-SWE
Publication class	Field Guide / Canonical Living Overview Guide
Skill levels	L1 Foundational; L2 Practitioner; L3 Advanced; L4 Frontier
Tags	RAG, retrieval, grounding, citations, memory, source authority, embeddings, GraphRAG, knowledge engineering, access-aware retrieval
Canonical route	/library/field-guides/mythos-fg-ai-0008/

Living publication

Corrections, expanded laboratories, improved diagrams, authority changes, and new engineering evidence should revise this permanent publication rather than create disconnected replacements.

CANONICAL LIVING OVERVIEW GUIDE

AI Tools, Skills, MCP, Plugins, and Capability Security

A capability integration guide covering tools, functions, skills, plugins, MCP clients and servers, resources, prompts, transports, authorization, schemas, discovery, sandboxing, capability policy, supply chain, observability, evaluation, and incident response.

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-SEC; MYTHOS-SWE; MYTHOS-CLD
Audience	Agent, AI platform, MCP, plugin, security, software, and integration engineers.
Prerequisites	APIs, JSON, OAuth, software security, agent architecture, sandboxing, and distributed systems.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Design tool and capability contracts with typed inputs, outputs, errors, authority, and side effects.

Implement MCP clients and servers with protocol lifecycle, discovery, transports, and authorization.

Separate tools, skills, prompts, plugins, and applications according to trust and execution semantics.

Enforce least privilege, confirmation, isolation, provenance, and supply-chain controls.

Evaluate tool use, recovery, security, interoperability, and verified completion.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Capability architecture and terminology

Define the different ways AI systems acquire actions and external context.

Chapter operating position
Define the different ways AI systems acquire actions and external context.

1.1 Functions and tools

Functions and tools must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Expose bounded operations with typed arguments, deterministic validation, errors, side effects, and results. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for functions and tools.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating functions and tools as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for functions and tools.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.2 Skills and workflows

Skills and workflows must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Package instructions, domain knowledge, tools, policies, templates, tests, and multi-step procedures. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for skills and workflows.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating skills and workflows as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for skills and workflows.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.3 Plugins and extensions

Plugins and extensions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Install code or services that add capabilities, UI, data, providers, runtimes, and lifecycle hooks. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for plugins and extensions.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating plugins and extensions as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for plugins and extensions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

1.4 Resources and prompts

Resources and prompts must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Provide contextual data and reusable interaction templates without granting execution authority. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for resources and prompts.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating resources and prompts as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for resources and prompts.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 01 laboratory and review

Practical laboratory
Classify twenty example capabilities as tool, resource, prompt, skill, plugin, or application and justify security boundaries.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore portable capability packages with machine-readable assurance metadata.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

MCP architecture and protocol lifecycle

Implement interoperable model-context clients and servers.

Chapter operating position
Implement interoperable model-context clients and servers.

2.1 Client, server, and host roles

Client, server, and host roles must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Separate user-facing application, protocol client, capability server, model, and approval boundary. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for client, server, and host roles.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating client, server, and host roles as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for client, server, and host roles.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.2 Initialization and capability negotiation

Initialization and capability negotiation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Exchange protocol version, features, implementation identity, instructions, and readiness. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for initialization and capability negotiation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating initialization and capability negotiation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for initialization and capability negotiation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.3 Tools, resources, and prompts

Tools, resources, and prompts must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. List, read, call, notify changes, validate schemas, report progress, and return structured content. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tools, resources, and prompts.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating tools, resources, and prompts as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tools, resources, and prompts.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

2.4 Lifecycle and compatibility

Lifecycle and compatibility must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Handle versions, feature support, deprecation, cancellation, errors, reconnect, and shutdown. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for lifecycle and compatibility.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating lifecycle and compatibility as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for lifecycle and compatibility.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 02 laboratory and review

Practical laboratory
Build a minimal MCP-like JSON-RPC client and server with initialization, tool discovery, schema validation, calls, errors, and shutdown.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore stateless protocol cores, long-running tasks, apps, and enterprise extension governance.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Transport, sessions, and interoperability

Move protocol messages reliably across local and remote boundaries.

Chapter operating position
Move protocol messages reliably across local and remote boundaries.

3.1 Standard input and output

Standard input and output must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use process lifecycle, framing, logging separation, environment, permissions, and crash handling. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for standard input and output.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating standard input and output as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for standard input and output.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.2 HTTP and streaming transport

HTTP and streaming transport must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use secure endpoints, sessions, authentication, origin, redirects, streaming, reconnect, and load balancing. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for http and streaming transport.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating http and streaming transport as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for http and streaming transport.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.3 Message and schema discipline

Message and schema discipline must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Validate JSON-RPC, IDs, notifications, method parameters, content, annotations, and unknown fields. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for message and schema discipline.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating message and schema discipline as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for message and schema discipline.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

3.4 Conformance and compatibility testing

Conformance and compatibility testing must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Test client and server versions, optional capabilities, malformed messages, timeouts, and cancellation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for conformance and compatibility testing.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating conformance and compatibility testing as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for conformance and compatibility testing.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 03 laboratory and review

Practical laboratory
Run compatibility tests between two clients and servers with missing capabilities, invalid schemas, duplicate IDs, and interrupted streams.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore capability federation and transport-independent agent communications.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Authorization, consent, and delegated authority

Ensure the agent cannot obtain or exercise more authority than intended.

Chapter operating position
Ensure the agent cannot obtain or exercise more authority than intended.

4.1 Identity and client registration

Identity and client registration must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Authenticate users, hosts, clients, servers, workloads, and administrators with stable identities. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for identity and client registration.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating identity and client registration as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for identity and client registration.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.2 OAuth and token security

OAuth and token security must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use current flows, PKCE, audiences, scopes, redirect validation, short lifetimes, rotation, and revocation. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for oauth and token security.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating oauth and token security as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for oauth and token security.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.3 Capability and action scopes

Capability and action scopes must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Limit tools, resources, operations, targets, data, environment, duration, rate, and side effects. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for capability and action scopes.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating capability and action scopes as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for capability and action scopes.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

4.4 User confirmation and policy

User confirmation and policy must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Require clear approval for sensitive, destructive, external, costly, or privacy-impacting actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for user confirmation and policy.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating user confirmation and policy as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for user confirmation and policy.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 04 laboratory and review

Practical laboratory
Design authorization for a remote capability server and test token theft, wrong audience, overbroad scope, stale consent, and revocation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore intent-bound capabilities and cryptographically constrained delegated authority.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Tool contracts, execution, and recovery

Make tool use deterministic, inspectable, and recoverable.

Chapter operating position
Make tool use deterministic, inspectable, and recoverable.

5.1 Typed arguments and validation

Typed arguments and validation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use JSON Schema, enums, identifiers, limits, defaults, canonicalization, and rejection. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for typed arguments and validation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating typed arguments and validation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for typed arguments and validation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.2 Side effects and transactions

Side effects and transactions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Declare read-only, idempotent, reversible, destructive, external, or long-running behavior. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for side effects and transactions.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating side effects and transactions as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for side effects and transactions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.3 Progress, cancellation, and timeouts

Progress, cancellation, and timeouts must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Report state, checkpoints, deadlines, partial results, cleanup, compensation, and retry policy. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for progress, cancellation, and timeouts.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating progress, cancellation, and timeouts as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for progress, cancellation, and timeouts.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

5.4 Output and evidence

Output and evidence must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Return structured results, content, artifacts, state changes, citations, warnings, uncertainty, and audit IDs. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for output and evidence.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating output and evidence as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for output and evidence.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 05 laboratory and review

Practical laboratory
Implement a transactional tool with preconditions, confirmation, idempotency, progress, cancellation, rollback, and evidence.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore effect systems and formally verified tool contracts.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Sandboxing, isolation, and capability policy

Contain untrusted code, tools, plugins, and model-generated actions.

Chapter operating position
Contain untrusted code, tools, plugins, and model-generated actions.

6.1 Process and OS isolation

Process and OS isolation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Use users, containers, sandboxes, filesystems, networks, syscalls, resources, devices, and secrets. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for process and os isolation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating process and os isolation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for process and os isolation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.2 Network and data egress

Network and data egress must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Allowlist destinations, protocols, DNS, proxies, uploads, downloads, telemetry, and external side effects. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for network and data egress.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating network and data egress as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for network and data egress.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.3 File and repository permissions

File and repository permissions must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Limit roots, read and write sets, symlinks, temporary files, executable content, and sensitive paths. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for file and repository permissions.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating file and repository permissions as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for file and repository permissions.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

6.4 Runtime policy and approval

Runtime policy and approval must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Evaluate model, tool, arguments, target, risk, user state, environment, and planned side effects before execution. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for runtime policy and approval.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating runtime policy and approval as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for runtime policy and approval.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 06 laboratory and review

Practical laboratory
Create a capability policy for a coding agent and prove it blocks secret files, unexpected networks, destructive commands, and privilege escalation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore hardware-isolated agent execution and capability-secure operating systems.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Supply chain, trust, and security threats

Treat capability packages and remote servers as software suppliers.

Chapter operating position
Treat capability packages and remote servers as software suppliers.

7.1 Discovery and installation

Discovery and installation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Verify publisher, source, license, version, dependencies, signature, provenance, permissions, and review. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for discovery and installation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating discovery and installation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for discovery and installation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.2 Prompt injection and confused deputy

Prompt injection and confused deputy must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Protect against malicious resources, tool outputs, names, descriptions, schemas, and cross-server influence. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for prompt injection and confused deputy.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating prompt injection and confused deputy as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for prompt injection and confused deputy.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.3 Server and plugin compromise

Server and plugin compromise must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Detect changed behavior, excessive data, hidden side effects, credential abuse, persistence, and update attacks. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for server and plugin compromise.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating server and plugin compromise as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for server and plugin compromise.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

7.4 Revocation and quarantine

Revocation and quarantine must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Disable capability, revoke tokens, preserve evidence, block versions, restore configuration, and notify users. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for revocation and quarantine.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating revocation and quarantine as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for revocation and quarantine.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 07 laboratory and review

Practical laboratory
Red-team a capability registry with malicious descriptions, schema tricks, dependency changes, update compromise, and data exfiltration.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore signed capability transparency logs and reputation based on reproducible evaluation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Evaluation, observability, and governance

Prove that capabilities improve outcomes without unacceptable authority or failure.

Chapter operating position
Prove that capabilities improve outcomes without unacceptable authority or failure.

8.1 Tool-use evaluation

Tool-use evaluation must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Measure selection, argument correctness, completion, recovery, cost, latency, side effects, and prohibited actions. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for tool-use evaluation.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating tool-use evaluation as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for tool-use evaluation.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.2 Telemetry and audit

Telemetry and audit must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Record discovery, authorization, call, arguments, policy, approval, progress, result, state change, error, and rollback. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for telemetry and audit.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Implementation sketch

```
tool:
  name: deploy_candidate
  input_schema:
    type: object
    required: [environment, artifact_digest, change_id]
  effects:
    class: reversible-production-change
    idempotent: true
  authorization:
    scopes: [deploy:canary]
    confirmation: required
  execution:
    timeout_seconds: 300
    rollback: automatic-on-gate-failure
```

Failure patterns

- Treating telemetry and audit as a model capability claim disconnected from complete system behavior.
- Using one benchmark, model judge, or successful demonstration as proof of production readiness.
- Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.
- Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.
- Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.
- Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for telemetry and audit.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.3 Registry and lifecycle

Registry and lifecycle must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Track identity, owner, versions, compatibility, permissions, evaluations, incidents, deprecation, and retirement. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

- Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for registry and lifecycle.
- Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.
- Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.
- Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.
- Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.
- Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

- Treating registry and lifecycle as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for registry and lifecycle.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

8.4 Governance and ecosystem policy

Governance and ecosystem policy must be treated as an observable AI-system mechanism rather than a model label, benchmark claim, prompt trick, or framework feature. Define publication, review, exception, update, vulnerability, data, commercial, and dispute rules. The implementation should name authoritative inputs, data and model versions, identities, state transitions, permissions, resource limits, telemetry, failure behavior, uncertainty, rollback, and acceptance criteria.

This guide traces the subject through the host, client, server or plugin, discovery, authorization, typed call, execution, state change, evidence, and recovery chain. A fluent response, high aggregate score, successful tool call, or green service dashboard is not sufficient proof. Intended behavior must be reconciled with hidden tests, source evidence, negative and adversarial cases, latency and resource measurements, user-visible results, and residual limitations.

Implementation begins with a small, inspectable baseline and explicit invariants. Introduce one model, dataset, retrieval source, tool, memory tier, optimization, or permission at a time; preserve before-state evidence; test expected and prohibited behavior; and retain a reversible path. Generated plans and model judgments remain subject to deterministic validation and human authority.

Troubleshooting locates the first divergence from the expected contract or state machine. Account for tokenizer and template mismatch, stale data, context loss, model nondeterminism, caching, quantization, scheduling, permissions, prompt injection, missing telemetry, partial tool effects, and distribution shift. Completion requires reproducibility, causal evidence, validated recovery, and clear disclosure of uncertainty.

Engineering practices

Define the objective, authority, data, model, owner, constraints, risks, and acceptance criteria for governance and ecosystem policy.

Separate model behavior from retrieval, tools, memory, policy, interface, and human oversight.

Version prompts, schemas, data, model artifacts, runtime configuration, evaluations, and release evidence.

Test nominal, negative, adversarial, long-context, degraded, overloaded, recovery, and rollback conditions.

Retain source, trajectory, tool, citation, metric, profile, decision, and user-outcome evidence.

Prefer least privilege, typed contracts, bounded budgets, staged rollout, abstention, and reversibility.

Failure patterns

Treating governance and ecosystem policy as a model capability claim disconnected from complete system behavior.

Using one benchmark, model judge, or successful demonstration as proof of production readiness.

Ignoring tokenizer, prompt template, source authority, permissions, cache, hardware, or version boundaries.

Allowing tools, plugins, retrieval content, or memory to redefine trusted instructions.

Optimizing latency, tokens, or cost without measuring quality, safety, and tail failures.

Declaring completion without hidden tests, evidence, residual limitations, rollback, and monitoring.

Validation and evidence

Method	Expected evidence
Examine	Requirements, authority, model, data, prompts, tools, memory, schemas, versions, and assumptions for governance and ecosystem policy.
Observe	Requests, selected context, trajectories, tool calls, model outputs, citations, caches, telemetry, resources, and user outcomes.
Test	Expected, prohibited, adversarial, malformed, long-context, overloaded, failed, recovery, and rollback cases.
Measure	Task quality, calibration, grounding, safety, latency, throughput, memory, tokens, cost, energy, and operator effort.
Reconcile	Intended system behavior against evaluated model, data, runtime, tools, sources, deployment, and residual risk.

Chapter 08 laboratory and review

Practical laboratory
Build a capability evaluation harness and release gate for three tools with hidden tests and security scenarios.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop a governed capability fabric spanning MCP, plugins, local tools, skills, and multi-agent runtimes.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. Model Context Protocol - Model Context Protocol Specification 2025-11-25
Role: Authoritative protocol requirements for resources, prompts, tools, transports, authorization, and lifecycle.
Verified: 2026-07-26

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Living publication

Corrections, expanded laboratories, improved diagrams, authority changes, and new engineering evidence should revise this permanent publication rather than create disconnected replacements.

CANONICAL LIVING OVERVIEW GUIDE

Agent Harnesses, Multi-Harness Fabrics, and Runtime Isolation

A frontier runtime guide defining agent harnesses as governed execution authorities and multi-harness fabrics as distributed systems for routing missions across isolated workspaces, tools, models, credentials, memory, sandboxes, and evidence planes.

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-SEC; MYTHOS-SWE; MYTHOS-CLD
Audience	Agent-runtime architects, AI platform engineers, security engineers, software-development platform teams, and advanced automation practitioners.
Prerequisites	Agentic systems, operating systems, containers, distributed systems, identity, software delivery, and security architecture.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Define a harness contract spanning model, context, tools, workspace, policy, state, telemetry, and lifecycle.

Compose multiple heterogeneous harnesses into a governed fabric with typed handoffs and deterministic mission state.

Isolate files, networks, credentials, processes, accelerators, models, and tenants according to risk.

Recover from harness, tool, model, worker, and orchestration failure without losing evidence or authority.

Evaluate fabric safety, throughput, reproducibility, blast radius, cost, and verified completion.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Harness anatomy and execution contract

Define the boundary that converts a model into an operational worker.

Chapter operating position
Define the boundary that converts a model into an operational worker.

1.1 Model and provider adapter

Model and provider adapter must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Normalize messages, tool schemas, streaming, structured output, token accounting, errors, and provider limits. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for model and provider adapter.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating model and provider adapter as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for model and provider adapter.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.2 Context and memory adapter

Context and memory adapter must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Provide task state, source-grounded context, private scratch, shared memory, compaction, and freshness. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for context and memory adapter.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating context and memory adapter as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for context and memory adapter.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.3 Tool and capability adapter

Tool and capability adapter must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Expose least-privilege operations with typed arguments, side effects, approvals, cancellation, and evidence. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for tool and capability adapter.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating tool and capability adapter as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for tool and capability adapter.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.4 Workspace and lifecycle

Workspace and lifecycle must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Create isolated files, repository state, processes, checkpoints, cleanup, retention, and terminal outcomes. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for workspace and lifecycle.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating workspace and lifecycle as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for workspace and lifecycle.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 01 laboratory and review

Practical laboratory
Implement a minimal harness contract and prove that an equivalent mission can run through two model adapters without changing tool authority.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore formally specified harness interfaces and proof-carrying execution.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Multi-harness fabric architecture

Coordinate heterogeneous harnesses without collapsing them into one privileged monolith.

Chapter operating position
Coordinate heterogeneous harnesses without collapsing them into one privileged monolith.

2.1 Fabric control plane

Fabric control plane must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Manage mission graphs, scheduling, identities, policies, budgets, capability catalogs, state, and approvals. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for fabric control plane.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating fabric control plane as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for fabric control plane.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.2 Harness data plane

Harness data plane must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Execute bounded work, emit observations, stage artifacts, report health, and accept cancellation or compensation. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for harness data plane.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

Treating harness data plane as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for harness data plane.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.3 Typed handoffs and artifacts

Typed handoffs and artifacts must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Exchange task contracts, claims, evidence, patches, tests, plans, models, and unresolved conditions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for typed handoffs and artifacts.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating typed handoffs and artifacts as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for typed handoffs and artifacts.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.4 Federation and interoperability

Federation and interoperability must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Bridge local harnesses, remote agents, MCP capabilities, A2A peers, and human operators. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for federation and interoperability.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating federation and interoperability as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for federation and interoperability.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 02 laboratory and review

Practical laboratory
Build a three-harness fabric with research, implementation, and verification roles and a deterministic fan-in contract.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore federated multi-organization fabrics with A2A discovery and signed capability advertisements.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Isolation and sandbox hierarchy

Select isolation according to code, data, tool, model, and infrastructure risk.

Chapter operating position
Select isolation according to code, data, tool, model, and infrastructure risk.

3.1 Process and user isolation

Process and user isolation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use separate identities, environment, resource limits, syscall policy, file roots, and process trees. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for process and user isolation.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating process and user isolation as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for process and user isolation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.2 Container, microVM, and WASM isolation

Container, microVM, and WASM isolation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Compare startup, kernel sharing, device access, networking, snapshotting, and escape risk. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for container, microvm, and wasm isolation.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating container, microvm, and wasm isolation as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for container, microvm, and wasm isolation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.3 Workspace and repository isolation

Workspace and repository isolation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use branches, worktrees, overlays, content-addressed snapshots, locks, and merge boundaries. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for workspace and repository isolation.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating workspace and repository isolation as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for workspace and repository isolation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.4 Accelerator and model isolation

Accelerator and model isolation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Control GPU partitions, memory, model weights, adapters, caches, prompts, and cross-tenant reuse. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for accelerator and model isolation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating accelerator and model isolation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for accelerator and model isolation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 03 laboratory and review

Practical laboratory
Run the same untrusted coding task under process, container, and microVM threat models and document residual exposure.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore confidential harnesses with attested code, encrypted memory, and policy-bound key release.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Identity, credentials, and capability authority

Bind every action to a workload identity and explicit grant.

Chapter operating position
Bind every action to a workload identity and explicit grant.

4.1 Harness and worker identity

Harness and worker identity must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Issue short-lived workload identities tied to runtime, mission, tenant, role, and environment. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for harness and worker identity.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating harness and worker identity as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for harness and worker identity.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.2 Credential brokering

Credential brokering must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Mint scoped tokens just in time, inject them without model visibility, rotate, revoke, and audit. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for credential brokering.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating credential brokering as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for credential brokering.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.3 Capability policy

Capability policy must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Limit tool, operation, target, data, network, duration, rate, cost, and side-effect class. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for capability policy.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating capability policy as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for capability policy.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.4 Delegation and human approval

Delegation and human approval must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Constrain subdelegation, require step-up approval, record intent, and prevent confused-deputy behavior. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for delegation and human approval.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating delegation and human approval as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for delegation and human approval.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 04 laboratory and review

Practical laboratory

Design a credential broker that permits read-only analysis and canary deployment but denies secret retrieval and production mutation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore cryptographic capabilities bound to signed mission plans and attested harness measurements.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Mission state, checkpoints, and event sourcing

Preserve authoritative progress independently of any one model context.

Chapter operating position
Preserve authoritative progress independently of any one model context.

5.1 Mission and task state machine

Mission and task state machine must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Represent queued, admitted, running, waiting, reviewing, approved, compensating, complete, and failed states. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for mission and task state machine.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating mission and task state machine as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for mission and task state machine.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.2 Event-sourced trajectory

Event-sourced trajectory must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record observation, plan, action, tool result, artifact, approval, state transition, cost, and causal links. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for event-sourced trajectory.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating event-sourced trajectory as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for event-sourced trajectory.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.3 Checkpoint and resume

Checkpoint and resume must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Persist repository, environment, memory, pending work, leases, and evidence for another harness to resume. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for checkpoint and resume.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating checkpoint and resume as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for checkpoint and resume.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.4 Consistency and conflict

Consistency and conflict must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use optimistic concurrency, leases, compare-and-swap, deduplication, merge policy, and human arbitration. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for consistency and conflict.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating consistency and conflict as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for consistency and conflict.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 05 laboratory and review

Practical laboratory

Interrupt a multi-step mission during tool execution and resume it on another harness without repeating an external side effect.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore transactional agent missions and verifiable replay across heterogeneous runtimes.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Scheduling, capacity, and placement

Place work according to capability, locality, risk, resources, and deadlines.

Chapter operating position
Place work according to capability, locality, risk, resources, and deadlines.

6.1 Capability-aware scheduling

Capability-aware scheduling must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Match task requirements to model, tools, operating system, accelerator, data location, and permissions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for capability-aware scheduling.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating capability-aware scheduling as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for capability-aware scheduling.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.2 Resource and quota scheduling

Resource and quota scheduling must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Allocate CPU, memory, GPU, tokens, provider rate, tool concurrency, storage, and network budgets. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for resource and quota scheduling.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating resource and quota scheduling as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for resource and quota scheduling.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.3 Priority, fairness, and preemption

Priority, fairness, and preemption must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Protect interactive work, critical missions, tenant fairness, deadlines, and resumable background work. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for priority, fairness, and preemption.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating priority, fairness, and preemption as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for priority, fairness, and preemption.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.4 Locality and sovereign placement

Locality and sovereign placement must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Keep sensitive data, models, artifacts, or tools inside approved devices, sites, regions, or trust domains. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for locality and sovereign placement.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating locality and sovereign placement as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for locality and sovereign placement.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 06 laboratory and review

Practical laboratory
Build a scheduler that routes ten tasks across local, cloud, GPU, restricted, and low-cost harness pools under quotas.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore market-like model and harness scheduling constrained by sovereignty, risk, energy, and evidence quality.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Failure containment, recovery, and compensation

Keep one faulty worker or tool from corrupting the mission or surrounding systems.

Chapter operating position
Keep one faulty worker or tool from corrupting the mission or surrounding systems.

7.1 Harness and worker failure

Harness and worker failure must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Detect heartbeat loss, deadlock, resource exhaustion, corrupt state, model failure, and sandbox crash. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for harness and worker failure.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating harness and worker failure as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for harness and worker failure.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.2 Tool and dependency failure

Tool and dependency failure must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Handle timeouts, partial effects, duplicate responses, stale data, rate limits, and unavailable services. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for tool and dependency failure.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating tool and dependency failure as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for tool and dependency failure.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.3 Compensation and rollback

Compensation and rollback must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Reverse file, repository, cloud, deployment, identity, and workflow effects through explicit compensators. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for compensation and rollback.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating compensation and rollback as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for compensation and rollback.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.4 Quarantine and incident response

Quarantine and incident response must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Freeze artifacts, revoke credentials, preserve evidence, isolate versions, and rebuild trusted state. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for quarantine and incident response.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating quarantine and incident response as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for quarantine and incident response.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 07 laboratory and review

Practical laboratory
Inject worker loss, duplicate completion, partial cloud mutation, and corrupted checkpoint into one mission and recover safely.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore self-healing harness pools with independent recovery agents and immutable evidence.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Fabric assurance, observability, and evolution

Measure the fabric as a safety-critical distributed execution platform.

Chapter operating position
Measure the fabric as a safety-critical distributed execution platform.

8.1 Trace and evidence model

Trace and evidence model must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Correlate mission, task, harness, model, context, tool, artifact, approval, cost, and outcome. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for trace and evidence model.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating trace and evidence model as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for trace and evidence model.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.2 Evaluation and chaos testing

Evaluation and chaos testing must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Test permissions, isolation, long horizons, race conditions, worker loss, stale state, and malicious inputs. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for evaluation and chaos testing.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
mission:
  id: mission-042
  state: admitted
  harnesses:
    planner:
      model_class: frontier-reasoner
      capabilities: [read:repo, write:plan]
    implementer:
      isolation: microvm
      capabilities: [read:repo, write:worktree, execute:test]
    verifier:
      isolation: separate-image
      capabilities: [read:candidate, execute:hidden-tests]
  fan_in:
    requires: [signed-plan, candidate-patch, test-evidence, independent-review]
  production_effects:
    default: deny
```

Failure patterns

- Treating evaluation and chaos testing as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for evaluation and chaos testing.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.3 Release and compatibility

Release and compatibility must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Version harness contracts, adapters, images, tools, schemas, policies, models, and migration paths. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for release and compatibility.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating release and compatibility as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for release and compatibility.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.4 Frontier governance

Frontier governance must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Separate stable fabric primitives from experimental autonomy, protocols, schedulers, and self-modification. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission contract, fabric control plane, harness placement, context, capability grant, execution, checkpoint, evidence, and verified outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for frontier governance.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating frontier governance as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for frontier governance.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 08 laboratory and review

Practical laboratory

Create a release qualification suite for a harness runtime and execute isolation, replay, failover, and prohibited-action tests.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop a multi-harness operating system with typed effects, federated identity, and continuous assurance.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy

Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. Model Context Protocol - Model Context Protocol Specification 2025-11-25
Role: Stable protocol baseline for tool, resource, prompt, transport, authorization, lifecycle, and capability integration.
Verified: 2026-07-26
Official source: https://modelcontextprotocol.io/specification/2025-11-25

02. Model Context Protocol - The 2026 MCP Roadmap
Role: Current roadmap for transport scalability, agent communication, governance maturation, and enterprise readiness.
Verified: 2026-07-26
Official source: https://blog.modelcontextprotocol.io/posts/2026-mcp-roadmap/

03. Agent2Agent Protocol - Agent2Agent Protocol Specification 1.0
Role: Open protocol for agent discovery, communication, task delegation, status, artifacts, and interoperability.
Verified: 2026-07-26
Official source: https://a2a-protocol.org/v1.0.0/

04. NIST - Artificial Intelligence Risk Management Framework 1.0
Role: Govern, Map, Measure, and Manage framework for trustworthy AI risk.
Verified: 2026-07-26

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-CLD; MYTHOS-DAT; MYTHOS-SWE
Audience	Agent architects, distributed-systems engineers, AI platform teams, model-routing engineers, and advanced software-development organizations.
Prerequisites	Agent runtimes, distributed systems, evaluation, model capabilities, queues, concurrency, and observability.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Decompose complex missions into parallelizable, dependency-aware, verifiable work.

Route roles and tasks across heterogeneous local and cloud models according to capability, cost, risk, and context.

Coordinate hundreds of workers through queues, leases, backpressure, quotas, and deterministic fan-in.

Prevent parallelism from multiplying duplicated work, correlated errors, context leakage, and unverified claims.

Measure useful parallel efficiency, evidence diversity, solution quality, reliability, and total system cost.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Parallelism taxonomy and mission graphs

Identify where parallel work creates genuine independence and where coordination dominates.

Chapter operating position
Identify where parallel work creates genuine independence and where coordination dominates.

1.1 Task DAGs and dependency analysis

Task DAGs and dependency analysis must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Separate prerequisites, independent branches, barriers, critical paths, optional work, and validation gates. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for task dags and dependency analysis.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating task dags and dependency analysis as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for task dags and dependency analysis.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.2 Fan-out and fan-in

Fan-out and fan-in must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Dispatch bounded subtasks and reconcile typed results through deterministic aggregation. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for fan-out and fan-in.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

Treating fan-out and fan-in as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for fan-out and fan-in.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.3 Pipeline and streaming parallelism

Pipeline and streaming parallelism must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Overlap research, implementation, tests, simulation, review, and deployment evidence. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for pipeline and streaming parallelism.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating pipeline and streaming parallelism as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for pipeline and streaming parallelism.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.4 Speculative and search parallelism

Speculative and search parallelism must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Explore alternative plans, patches, hypotheses, tool paths, and models before selecting. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for speculative and search parallelism.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating speculative and search parallelism as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for speculative and search parallelism.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 01 laboratory and review

Practical laboratory
Convert a monolithic engineering task into a DAG and compare serial, fan-out, pipeline, and speculative execution.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore automatically learned mission graphs constrained by formal dependencies.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Agent roles, teams, and supervisory topology

Design organizational structure for machine workers rather than assigning arbitrary personas.

Chapter operating position
Design organizational structure for machine workers rather than assigning arbitrary personas.

2.1 Supervisor and worker hierarchy

Supervisor and worker hierarchy must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Assign decomposition, scheduling, conflict resolution, verification, escalation, and final decision authority. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for supervisor and worker hierarchy.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating supervisor and worker hierarchy as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for supervisor and worker hierarchy.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.2 Specialist arrays

Specialist arrays must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use architecture, security, implementation, testing, documentation, operations, and domain specialists. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for specialist arrays.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

Treating specialist arrays as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for specialist arrays.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.3 Peer review and debate

Peer review and debate must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Generate independent analyses, adversarial critiques, counterexamples, and reconciled conclusions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for peer review and debate.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating peer review and debate as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for peer review and debate.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.4 Dynamic team formation

Dynamic team formation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Instantiate or retire roles according to uncertainty, failures, workload, and evidence gaps. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for dynamic team formation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating dynamic team formation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for dynamic team formation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 02 laboratory and review

Practical laboratory
Run a supervisor with four specialists and compare majority vote, evidence-weighted review, and deterministic verification.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore self-organizing teams with bounded authority and measurable role utility.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Multi-model portfolio and routing

Use model heterogeneity as an engineering resource rather than a branding choice.

Chapter operating position
Use model heterogeneity as an engineering resource rather than a branding choice.

3.1 Capability profiles

Capability profiles must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Measure reasoning, code, retrieval, tool use, context, language, modality, safety, latency, and cost. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for capability profiles.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating capability profiles as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for capability profiles.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.2 Role-to-model mapping

Role-to-model mapping must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Assign strong planners, fast workers, local private models, critics, judges, and domain adapters. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for role-to-model mapping.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

- Treating role-to-model mapping as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for role-to-model mapping.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.3 Cascade and escalation

Cascade and escalation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Start with low-cost or local models and escalate when confidence, complexity, or verification demands it. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for cascade and escalation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating cascade and escalation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for cascade and escalation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.4 Ensemble diversity and correlation

Ensemble diversity and correlation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Measure whether model families produce independent evidence or repeat the same failure. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for ensemble diversity and correlation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating ensemble diversity and correlation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for ensemble diversity and correlation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 03 laboratory and review

Practical laboratory
Create a routing matrix for five models and evaluate static roles, cascades, and adaptive selection on hidden tasks.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore online model routing using calibrated capability, uncertainty, current load, and task embeddings.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Distributed scheduling and extreme scale

Control large worker populations without overload or starvation.

Chapter operating position
Control large worker populations without overload or starvation.

4.1 Queues, leases, and work stealing

Queues, leases, and work stealing must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use durable admission, task claims, heartbeats, expiry, retries, locality, and duplicate suppression. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for queues, leases, and work stealing.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating queues, leases, and work stealing as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for queues, leases, and work stealing.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.2 Resource-aware placement

Resource-aware placement must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Allocate CPU, GPU, memory, context, tokens, rate limits, tools, and sovereign data access. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for resource-aware placement.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

Treating resource-aware placement as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for resource-aware placement.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.3 Backpressure and concurrency control

Backpressure and concurrency control must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Bound active workers, queue growth, tool contention, model saturation, and downstream fan-in. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for backpressure and concurrency control.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating backpressure and concurrency control as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for backpressure and concurrency control.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.4 Cohorts, quotas, and fairness

Cohorts, quotas, and fairness must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Share scarce models and accelerators across missions, teams, tenants, and priorities. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for cohorts, quotas, and fairness.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating cohorts, quotas, and fairness as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for cohorts, quotas, and fairness.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 04 laboratory and review

Practical laboratory

Simulate one thousand subtasks with worker loss, heterogeneous duration, limited model quotas, and a bounded fan-in service.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore Kueue-style admission for agent swarms and cross-cluster harness placement.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Context partitioning and shared state

Provide each worker enough information without cloning the entire mission history.

Chapter operating position
Provide each worker enough information without cloning the entire mission history.

5.1 Role-specific context views

Role-specific context views must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Project task contract, authoritative sources, dependencies, local state, and acceptance criteria. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for role-specific context views.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating role-specific context views as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for role-specific context views.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.2 Blackboard and shared memory

Blackboard and shared memory must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Publish claims, artifacts, questions, conflicts, evidence, and status through typed records. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for blackboard and shared memory.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

Treating blackboard and shared memory as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for blackboard and shared memory.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.3 Private scratch and confidentiality

Private scratch and confidentiality must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Separate local reasoning, restricted data, tenant context, and sensitive tool results. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for private scratch and confidentiality.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating private scratch and confidentiality as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for private scratch and confidentiality.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.4 Freshness and concurrency

Freshness and concurrency must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Detect stale plans, changed artifacts, conflicting edits, duplicated work, and inconsistent summaries. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for freshness and concurrency.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating freshness and concurrency as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for freshness and concurrency.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 05 laboratory and review

Practical laboratory

Partition a repository mission among ten workers and prove that no worker receives unrelated secrets or stale dependencies.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore transactional semantic memory and cryptographic access control for shared agent state.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Consensus, fan-in, and verification

Turn many outputs into one justified result without averaging errors.

Chapter operating position
Turn many outputs into one justified result without averaging errors.

6.1 Typed result contracts

Typed result contracts must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Require claims, evidence, artifacts, uncertainty, assumptions, tests, and unresolved issues. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for typed result contracts.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating typed result contracts as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for typed result contracts.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.2 Deterministic aggregation

Deterministic aggregation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Merge code, data, reports, and state through schemas, compilers, tests, and transaction rules. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for deterministic aggregation.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

- Treating deterministic aggregation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for deterministic aggregation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.3 Evidence-weighted consensus

Evidence-weighted consensus must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Prefer source authority, independent replication, stronger tests, and calibrated expertise over votes. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for evidence-weighted consensus.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating evidence-weighted consensus as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for evidence-weighted consensus.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.4 Conflict and minority findings

Conflict and minority findings must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Preserve dissent, reproduce disagreements, request targeted evidence, and escalate high-impact uncertainty. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for conflict and minority findings.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating conflict and minority findings as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for conflict and minority findings.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 06 laboratory and review

Practical laboratory

Aggregate twenty agent reports containing duplicates, conflicts, unsupported claims, and one critical minority finding.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore formal proof aggregation and verifier networks.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Reliability, failure domains, and recovery

Prevent correlated errors and cascading retries from overwhelming the system.

Chapter operating position
Prevent correlated errors and cascading retries from overwhelming the system.

7.1 Worker and supervisor failure

Worker and supervisor failure must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Recover leases, restart tasks, promote backups, preserve state, and avoid split-brain leadership. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for worker and supervisor failure.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating worker and supervisor failure as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for worker and supervisor failure.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.2 Correlated model failure

Correlated model failure must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Detect shared training artifacts, prompt bias, benchmark shortcuts, and synchronized hallucination. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for correlated model failure.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

Treating correlated model failure as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for correlated model failure.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.3 Retry and speculation storms

Retry and speculation storms must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use budgets, jitter, circuit breakers, deduplication, and global overload controls. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for retry and speculation storms.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating retry and speculation storms as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for retry and speculation storms.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.4 Mission checkpoint and compensation

Mission checkpoint and compensation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Resume after fabric outage, roll back external effects, and reconcile orphan artifacts. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for mission checkpoint and compensation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating mission checkpoint and compensation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for mission checkpoint and compensation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 07 laboratory and review

Practical laboratory

Inject supervisor loss, a shared-model systematic error, and a retry storm into a parallel mission.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore Byzantine-resilient agent collaboration for high-assurance environments.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Parallel efficiency, economics, and frontier scaling

Measure useful work rather than raw agent count.

Chapter operating position
Measure useful work rather than raw agent count.

8.1 Speedup and critical path

Speedup and critical path must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Measure wall time, serial fraction, queueing, synchronization, fan-in, and rework. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for speedup and critical path.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating speedup and critical path as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for speedup and critical path.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.2 Quality and evidence gain

Quality and evidence gain must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Measure solved tasks, critical failures, independent confirmations, coverage, and verified novelty. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for quality and evidence gain.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
parallel_policy:
  max_workers: 64
  max_model_calls: 400
  per_model_concurrency:
    local-fast: 24
    cloud-reasoner: 8
    verifier: 12
  queues:
    planning: {priority: 100, max_depth: 50}
    implementation: {priority: 50, max_depth: 200}
    verification: {priority: 90, max_depth: 100}
  stop_when:
    - critical_path_complete
    - marginal_verified_value_below: 0.05
    - budget_exhausted
```

Failure patterns

Treating quality and evidence gain as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for quality and evidence gain.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.3 Cost and resource efficiency

Cost and resource efficiency must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Track tokens, model calls, GPUs, tools, storage, networking, human review, and failed branches. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for cost and resource efficiency.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating cost and resource efficiency as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for cost and resource efficiency.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.4 Adaptive scale policy

Adaptive scale policy must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Increase or reduce agents according to uncertainty, marginal value, deadline, budget, and system health. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission DAG, task admission, role and model route, worker execution, shared state, fan-in, verification, cost, and completion chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 08 laboratory and review

Practical laboratory

Benchmark 1, 4, 16, and 64-agent configurations and report useful speedup, quality, cost, duplication, and fan-in burden.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop elastic multi-model supercomputing for reasoning with policy-constrained search and evidence-aware stopping.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. Agent2Agent Protocol - Agent2Agent Protocol Specification 1.0
Role: Open protocol for agent discovery, communication, task delegation, status, artifacts, and interoperability.
Verified: 2026-07-26
Official source: https://a2a-protocol.org/v1.0.0/

02. Model Context Protocol - The 2026 MCP Roadmap
Role: Current roadmap for transport scalability, agent communication, governance maturation, and enterprise readiness.
Verified: 2026-07-26
Official source: https://blog.modelcontextprotocol.io/posts/2026-mcp-roadmap/

03. Ray Project - Ray Core Documentation
Role: Distributed tasks, actors, placement, scheduling, resources, and fault tolerance.
Verified: 2026-07-26
Official source: https://docs.ray.io/en/latest/ray-core/walkthrough.html

04. Kubernetes - Kueue Documentation
Role: Kubernetes-native batch and AI workload queueing, admission, cohorts, and resource sharing.
Verified: 2026-07-26
Official source: https://kueue.sigs.k8s.io/

05. Temporal - Temporal Documentation
Role: Durable workflow execution, retries, timers, signals, state, and recovery.
Verified: 2026-07-26
Official source: https://docs.temporal.io/

06. NIST - Artificial Intelligence Risk Management Framework 1.0
Role: Govern, Map, Measure, and Manage framework for trustworthy AI risk.
Verified: 2026-07-26
Official source: https://nvlpubs.nist.gov/nistpubs/ai/nist.ai.100-1.pdf

07. NIST - NIST AI 600-1 - Generative Artificial Intelligence Profile
Role: Generative-AI risk profile and recommended actions.

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Dimension	Engineering position

Secondary domain	MYTHOS-CLD; MYTHOS-DAT; MYTHOS-SWE
Publication class	Field Guide / Canonical Living Overview Guide
Skill levels	L1 Foundational; L2 Practitioner; L3 Advanced; L4 Frontier
Tags	multi-agent, multi-model, parallelism, agent swarm, model routing, fan-out fan-in, distributed scheduling, speculative execution, supervisor, extreme scale
Canonical route	/library/field-guides/mythos-fg-ai-0011/

Living publication

Corrections, expanded laboratories, improved diagrams, authority changes, and new engineering evidence should revise this permanent publication rather than create disconnected replacements.

CANONICAL LIVING OVERVIEW GUIDE

AI Safety, Alignment, Red Teaming, Sycophancy, and Control

A practical-to-frontier safety guide covering risk governance, objective and instruction alignment, sycophancy, reward hacking, deceptive behavior, prompt injection, tool misuse, memory poisoning, red teaming, control architectures, human oversight, monitoring, and incident response.

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-SEC; MYTHOS-UX; MYTHOS-DAT
Audience	AI safety engineers, security teams, evaluators, product leaders, agent architects, and governance bodies.
Prerequisites	AI systems, evaluation, security architecture, human factors, software assurance, and risk management.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Translate abstract safety concerns into system-specific hazards, controls, evaluations, and accountable decisions.

Detect sycophancy, overcompliance, deception, reward hacking, goal drift, and unsafe tool behavior.

Build layered control using policy, permissions, verification, oversight, containment, and recovery.

Red-team models and agent systems across prompts, retrieval, memory, tools, identity, and environments.

Monitor safety in production and respond to incidents without hiding uncertainty or control limitations.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Safety objectives, hazards, and governance

Define acceptable behavior, prohibited outcomes, stakeholders, and risk authority.

Chapter operating position
Define acceptable behavior, prohibited outcomes, stakeholders, and risk authority.

1.1 System boundary and use context

System boundary and use context must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Separate base model, prompts, retrieval, memory, tools, agents, interface, humans, and deployment environment. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for system boundary and use context.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating system boundary and use context as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for system boundary and use context.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.2 Hazard and misuse analysis

Hazard and misuse analysis must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Identify harmful content, action, privacy loss, bias, deception, overreliance, autonomy, and systemic failures. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for hazard and misuse analysis.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating hazard and misuse analysis as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for hazard and misuse analysis.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.3 Risk ownership and decision rights

Risk ownership and decision rights must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Assign product, safety, security, legal, domain, operations, executive, and user authority. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for risk ownership and decision rights.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating risk ownership and decision rights as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for risk ownership and decision rights.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.4 Safety case and evidence

Safety case and evidence must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Link claims, controls, tests, monitoring, exceptions, limitations, and approval. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for safety case and evidence.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating safety case and evidence as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for safety case and evidence.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 01 laboratory and review

Practical laboratory

Build a safety case for an agent that can modify cloud infrastructure and identify claims that remain unproven.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore machine-readable assurance cases continuously updated by evaluations and incidents.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Instruction, objective, and preference alignment

Keep behavior bound to legitimate user intent and system policy.

Chapter operating position
Keep behavior bound to legitimate user intent and system policy.

2.1 Instruction hierarchy

Instruction hierarchy must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Resolve system, developer, user, tool, retrieved, and environmental instructions without authority confusion. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for instruction hierarchy.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating instruction hierarchy as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for instruction hierarchy.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.2 Goal decomposition and drift

Goal decomposition and drift must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Track parent objective, subgoals, constraints, terminal criteria, and unauthorized objective expansion. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for goal decomposition and drift.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating goal decomposition and drift as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for goal decomposition and drift.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.3 Preference conflict and pluralism

Preference conflict and pluralism must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Handle user, organization, law, domain, safety, and cultural differences explicitly. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for preference conflict and pluralism.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating preference conflict and pluralism as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for preference conflict and pluralism.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.4 Abstention and escalation

Abstention and escalation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Recognize insufficient evidence, conflicting authority, unsafe requests, and need for human decision. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for abstention and escalation.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating abstention and escalation as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for abstention and escalation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 02 laboratory and review

Practical laboratory
Test an agent with conflicting user, retrieved, tool, and policy instructions and verify consistent authority resolution.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore constitutional policy systems with user-visible, domain-specific, and jurisdiction-aware layers.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Sycophancy, truthfulness, and epistemic control

Prevent the system from optimizing agreement or confidence instead of evidence.

Chapter operating position
Prevent the system from optimizing agreement or confidence instead of evidence.

3.1 Belief and preference mirroring

Belief and preference mirroring must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Test whether outputs change to match asserted user views despite unchanged evidence. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for belief and preference mirroring.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating belief and preference mirroring as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for belief and preference mirroring.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.2 Confidence and uncertainty

Confidence and uncertainty must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Calibrate probabilities, distinguish fact from inference, cite sources, and avoid unsupported certainty. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for confidence and uncertainty.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating confidence and uncertainty as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for confidence and uncertainty.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.3 Contradiction and correction

Contradiction and correction must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Invite challenge, preserve dissent, update from evidence, and avoid defensive rationalization. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for contradiction and correction.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating contradiction and correction as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for contradiction and correction.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.4 Decision-interface design

Decision-interface design must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Present alternatives, assumptions, risks, and evidence rather than persuasive single-answer theater. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for decision-interface design.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating decision-interface design as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for decision-interface design.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 03 laboratory and review

Practical laboratory
Run controlled sycophancy tests that vary user belief, status, emotion, and requested conclusion while holding evidence constant.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore epistemic supervisors that optimize source-grounded truthfulness rather than conversational approval.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Agentic failure modes and control loss

Address risks introduced by planning, tools, memory, persistence, and delegation.

Chapter operating position
Address risks introduced by planning, tools, memory, persistence, and delegation.

4.1 Reward hacking and specification gaming

Reward hacking and specification gaming must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Detect proxy optimization, loopholes, hidden side effects, metric manipulation, and premature completion. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for reward hacking and specification gaming.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating reward hacking and specification gaming as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for reward hacking and specification gaming.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.2 Deception and situational behavior

Deception and situational behavior must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Test strategic concealment, evaluation awareness, inconsistent explanations, and hidden planning. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for deception and situational behavior.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating deception and situational behavior as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for deception and situational behavior.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.3 Tool misuse and excessive agency

Tool misuse and excessive agency must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Constrain destructive actions, broad searches, external communications, purchases, code execution, and infrastructure changes. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for tool misuse and excessive agency.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating tool misuse and excessive agency as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for tool misuse and excessive agency.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.4 Memory and persistence abuse

Memory and persistence abuse must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Prevent poisoned memories, unauthorized self-modification, credential retention, and durable policy bypass. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for memory and persistence abuse.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating memory and persistence abuse as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for memory and persistence abuse.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 04 laboratory and review

Practical laboratory
Design an agent task with exploitable acceptance criteria and verify whether the agent games the metric or completes the real objective.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore tripwires, interpretability-assisted control, and cryptographically bounded autonomy.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Safety architecture and layered control

Combine prevention, limitation, detection, response, and recovery.

Chapter operating position
Combine prevention, limitation, detection, response, and recovery.

5.1 Policy and capability controls

Policy and capability controls must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use typed tools, least privilege, target constraints, rate limits, budgets, and side-effect classifications. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for policy and capability controls.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating policy and capability controls as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for policy and capability controls.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.2 Independent verification

Independent verification must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Require deterministic checks, separate models, human review, sandbox tests, and evidence before high-impact actions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for independent verification.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating independent verification as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for independent verification.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.3 Containment and fail-safe behavior

Containment and fail-safe behavior must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Pause, isolate, revoke, degrade, fall back, or terminate on ambiguity, drift, or control failure. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for containment and fail-safe behavior.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating containment and fail-safe behavior as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for containment and fail-safe behavior.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.4 Human oversight and user control

Human oversight and user control must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Provide approvals, explanations, corrections, undo, activity history, preferences, and appeal. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for human oversight and user control.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating human oversight and user control as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for human oversight and user control.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 05 laboratory and review

Practical laboratory
Construct layered controls for a coding agent and prove that bypass of one layer does not authorize production deployment.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore runtime safety kernels outside model control.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Red teaming and adversarial evaluation

Test the full system using realistic attackers, environments, and failure chains.

Chapter operating position
Test the full system using realistic attackers, environments, and failure chains.

6.1 Threat-led campaign design

Threat-led campaign design must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use misuse cases, MITRE ATLAS, OWASP risks, incidents, architecture, and critical assets. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for threat-led campaign design.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating threat-led campaign design as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for threat-led campaign design.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.2 Prompt and context attacks

Prompt and context attacks must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Test jailbreaks, indirect injection, encoding, multilingual, multimodal, retrieved content, and memory. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for prompt and context attacks.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating prompt and context attacks as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for prompt and context attacks.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.3 Tool and environment attacks

Tool and environment attacks must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Test malicious servers, schemas, files, repositories, websites, dependencies, and compromised peers. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for tool and environment attacks.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating tool and environment attacks as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for tool and environment attacks.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.4 Adaptive and multi-turn attacks

Adaptive and multi-turn attacks must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Escalate gradually, exploit state, social pressure, role confusion, fatigue, and long-horizon weaknesses. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for adaptive and multi-turn attacks.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating adaptive and multi-turn attacks as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for adaptive and multi-turn attacks.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 06 laboratory and review

Practical laboratory
Run an end-to-end red-team campaign against an agent with retrieval, MCP tools, memory, and external messaging.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore autonomous adversary agents constrained by safe cyber ranges and human campaign authority.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Monitoring, incident response, and recovery

Detect safety degradation after release and restore trustworthy operation.

Chapter operating position
Detect safety degradation after release and restore trustworthy operation.

7.1 Safety telemetry

Safety telemetry must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record model, prompt classes, policy, tool decisions, approvals, refusals, overrides, incidents, and user outcomes. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for safety telemetry.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating safety telemetry as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for safety telemetry.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.2 Drift and change detection

Drift and change detection must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Track model, prompt, data, tools, memory, users, environment, and distribution shifts. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for drift and change detection.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating drift and change detection as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for drift and change detection.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.3 Incident command and containment

Incident command and containment must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Disable models, tools, memory, routes, tenants, or autonomy; preserve evidence and notify owners. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for incident command and containment.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating incident command and containment as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for incident command and containment.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.4 Correction and trust restoration

Correction and trust restoration must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Patch policy, data, model, runtime, evaluation, permissions, and communication before controlled re-release. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for correction and trust restoration.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating correction and trust restoration as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for correction and trust restoration.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 07 laboratory and review

Practical laboratory
Exercise a safety incident caused by a model update and indirect prompt injection, including containment and requalification.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore continuous safety canaries and automated rollback triggered by verified critical failures.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Frontier assurance and open problems

Distinguish operational controls from unresolved research questions.

Chapter operating position
Distinguish operational controls from unresolved research questions.

8.1 Interpretability and internal monitoring

Interpretability and internal monitoring must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use representations, activations, probes, attribution, anomaly detection, and uncertainty with limitations. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for interpretability and internal monitoring.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating interpretability and internal monitoring as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for interpretability and internal monitoring.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.2 Scalable oversight

Scalable oversight must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Evaluate decomposition, debate, amplification, recursive review, and verifier models. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for scalable oversight.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
action_policy:
  action: deploy_production
  risk: critical
  prerequisites:
    - user_intent_confirmed
    - plan_signature_valid
    - hidden_tests_pass
    - independent_security_review
    - rollback_verified
  model_may_approve: false
  human_roles: [service-owner, release-authority]
  on_ambiguity: deny-and-escalate
```

Failure patterns

- Treating scalable oversight as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for scalable oversight.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.3 Robust alignment and power-seeking

Robust alignment and power-seeking must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Study generalization, corrigibility, shutdown behavior, resource seeking, and deceptive alignment. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for robust alignment and power-seeking.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating robust alignment and power-seeking as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for robust alignment and power-seeking.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.4 Governance and responsible scaling

Governance and responsible scaling must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Tie capability thresholds, evaluation, access, compute, deployment, monitoring, and external review. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the use context, hazard, policy, model behavior, tool authority, oversight, telemetry, incident, and recovery chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for governance and responsible scaling.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating governance and responsible scaling as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for governance and responsible scaling.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 08 laboratory and review

Practical laboratory

Create a frontier-risk register separating deployable controls, research prototypes, unknowns, and unsupported claims.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop transparent safety control planes with independent authority over models, tools, memory, and deployment.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. NIST - Artificial Intelligence Risk Management Framework 1.0
Role: Govern, Map, Measure, and Manage framework for trustworthy AI risk.
Verified: 2026-07-26
Official source: https://nvlpubs.nist.gov/nistpubs/ai/nist.ai.100-1.pdf

02. NIST - NIST AI 600-1 - Generative Artificial Intelligence Profile
Role: Generative-AI risk profile and recommended actions.
Verified: 2026-07-26
Official source: https://nvlpubs.nist.gov/nistpubs/ai/NIST.AI.600-1.pdf

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-DAT; MYTHOS-SEC; MYTHOS-CLD
Audience	AI platform, observability, evaluation, security, SRE, agent-runtime, and governance teams.
Prerequisites	OpenTelemetry, distributed tracing, logs, metrics, AI systems, evaluation, privacy, and distributed systems.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Define a canonical event and trace model spanning missions, agents, models, context, tools, memory, and outcomes.

Correlate operational telemetry with evaluation evidence, user experience, cost, and safety.

Preserve reproducible trajectories without indiscriminately logging sensitive prompts and content.

Detect model, context, tool, agent, and orchestration failures through causal evidence.

Use telemetry for release gates, incident response, audit, replay, and continuous improvement.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Observability architecture and objectives

Define which questions telemetry must answer and who may access it.

Chapter operating position
Define which questions telemetry must answer and who may access it.

1.1 Operational and assurance questions

Operational and assurance questions must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Support latency, reliability, cost, quality, safety, debugging, audit, and incident decisions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for operational and assurance questions.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating operational and assurance questions as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for operational and assurance questions.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.2 Telemetry planes and stores

Telemetry planes and stores must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Separate high-cardinality traces, metrics, events, artifacts, evaluation records, and immutable evidence. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for telemetry planes and stores.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

Treating telemetry planes and stores as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for telemetry planes and stores.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.3 Identity and correlation

Identity and correlation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Assign mission, task, agent, harness, model, request, session, tool, user, tenant, and artifact IDs. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for identity and correlation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating identity and correlation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for identity and correlation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.4 Ownership and access

Ownership and access must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Define platform, application, evaluator, security, privacy, support, and user visibility. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for ownership and access.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating ownership and access as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for ownership and access.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 01 laboratory and review

Practical laboratory
Create an observability requirements matrix for an agentic application and identify prohibited content collection.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore user-owned evidence vaults and federated telemetry.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Mission, agent, and harness tracing

Represent distributed agent work as a causal execution graph.

Chapter operating position
Represent distributed agent work as a causal execution graph.

2.1 Mission and task spans

Mission and task spans must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record objective, parent, dependencies, state, start, end, outcome, owner, and critical path. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for mission and task spans.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating mission and task spans as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for mission and task spans.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.2 Agent and harness spans

Agent and harness spans must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record role, runtime, model route, context version, capability set, resource placement, and health. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for agent and harness spans.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating agent and harness spans as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for agent and harness spans.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.3 Handoffs and links

Handoffs and links must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use span links or explicit edges for fan-out, fan-in, messages, shared artifacts, and retries. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for handoffs and links.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating handoffs and links as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for handoffs and links.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.4 State-transition events

State-transition events must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Capture queued, admitted, running, waiting, approved, compensating, failed, and completed transitions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for state-transition events.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating state-transition events as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for state-transition events.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 02 laboratory and review

Practical laboratory
Instrument a four-agent mission and reconstruct its critical path, fan-out, retries, and fan-in from telemetry.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore graph-native trace backends for extreme agent parallelism.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Model-call and token telemetry

Measure model behavior and resource use without confusing provider metrics with outcomes.

Chapter operating position
Measure model behavior and resource use without confusing provider metrics with outcomes.

3.1 Request configuration

Request configuration must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record provider, model, version, parameters, context length, output limit, tools, response format, and cache. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for request configuration.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating request configuration as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for request configuration.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.2 Latency decomposition

Latency decomposition must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Measure queue, network, prefill, first token, decode, tool wait, postprocessing, and end-to-end time. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for latency decomposition.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating latency decomposition as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for latency decomposition.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.3 Token and cost accounting

Token and cost accounting must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Track input, output, reasoning, cached, multimodal, embedding, provider cost, and internal chargeback. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for token and cost accounting.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating token and cost accounting as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for token and cost accounting.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.4 Output and finish state

Output and finish state must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record finish reason, validation, refusal, truncation, repair, retries, and user-visible completion. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for output and finish state.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating output and finish state as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for output and finish state.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 03 laboratory and review

Practical laboratory
Compare two model routes using task success, latency decomposition, token use, retries, and cost.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore hardware energy attribution and model-call carbon accounting.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Context, retrieval, memory, and grounding evidence

Explain what information influenced the model and whether it was authorized.

Chapter operating position
Explain what information influenced the model and whether it was authorized.

4.1 Context assembly

Context assembly must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record source IDs, versions, authority, freshness, selection score, token contribution, and redaction. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for context assembly.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating context assembly as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for context assembly.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.2 Retrieval and reranking

Retrieval and reranking must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Capture query, filters, candidates, rankings, permissions, citations, and cache behavior. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for retrieval and reranking.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating retrieval and reranking as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for retrieval and reranking.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.3 Memory access

Memory access must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record memory tier, key, purpose, consent, read, write, correction, expiry, and deletion. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for memory access.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating memory access as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for memory access.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.4 Grounding and claim support

Grounding and claim support must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Link output claims to sources, calculations, tool evidence, confidence, conflicts, and abstention. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for grounding and claim support.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating grounding and claim support as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for grounding and claim support.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 04 laboratory and review

Practical laboratory
Trace one answer from query through retrieval, reranking, context packing, output claims, and citation validation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore privacy-preserving influence tracing and proof-carrying grounded generation.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Tool, capability, and external-effect telemetry

Make model-initiated actions observable and reconstructable.

Chapter operating position
Make model-initiated actions observable and reconstructable.

5.1 Discovery and selection

Discovery and selection must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record available capabilities, descriptions, versions, policy filters, selected tool, and alternatives. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for discovery and selection.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating discovery and selection as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for discovery and selection.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.2 Authorization and approval

Authorization and approval must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record identity, scopes, policy, risk, user confirmation, approver, and expiration. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for authorization and approval.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating authorization and approval as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for authorization and approval.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.3 Invocation and result

Invocation and result must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record typed arguments, hashes or protected values, progress, duration, result, error, and evidence. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for invocation and result.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating invocation and result as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for invocation and result.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.4 Side effects and rollback

Side effects and rollback must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record state before, intended change, observed effect, compensation, residual change, and validation. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for side effects and rollback.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating side effects and rollback as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for side effects and rollback.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 05 laboratory and review

Practical laboratory

Instrument a canary deployment tool and prove exactly who authorized it, what changed, and how rollback was verified.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore cryptographically signed action receipts and effect ledgers.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Evaluation and quality telemetry

Connect live behavior to tests, benchmarks, and release decisions.

Chapter operating position
Connect live behavior to tests, benchmarks, and release decisions.

6.1 Evaluation run identity

Evaluation run identity must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record suite, cases, dataset, graders, model, system, environment, seed, version, and artifacts. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for evaluation run identity.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating evaluation run identity as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for evaluation run identity.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.2 Per-case and slice results

Per-case and slice results must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Capture task success, critical failures, safety, grounding, calibration, latency, and cost. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for per-case and slice results.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating per-case and slice results as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for per-case and slice results.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.3 Judge and human evidence

Judge and human evidence must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record rubric, judge model, expert, disagreement, confidence, comments, and adjudication. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for judge and human evidence.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating judge and human evidence as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for judge and human evidence.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.4 Production feedback loop

Production feedback loop must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Promote incidents, user corrections, failed trajectories, and drift into regression suites. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for production feedback loop.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating production feedback loop as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for production feedback loop.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 06 laboratory and review

Practical laboratory
Join production traces to an evaluation regression and identify the change that introduced a critical failure.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore continuously generated counterfactual evaluations from production trajectories.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 07

Privacy, security, and evidence integrity

Preserve useful evidence without creating a surveillance or secret-leakage system.

Chapter operating position
Preserve useful evidence without creating a surveillance or secret-leakage system.

7.1 Content collection policy

Content collection policy must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Choose metadata-only, sampled, redacted, encrypted, consented, or prohibited prompt and response logging. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for content collection policy.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating content collection policy as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for content collection policy.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.2 Sensitive data controls

Sensitive data controls must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Protect credentials, personal data, proprietary code, retrieved documents, model weights, and hidden policies. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for sensitive data controls.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating sensitive data controls as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for sensitive data controls.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.3 Integrity and provenance

Integrity and provenance must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Hash artifacts, sign releases, preserve parser and schema versions, control write access, and detect tampering. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for integrity and provenance.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating integrity and provenance as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for integrity and provenance.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

7.4 Retention and deletion

Retention and deletion must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Apply purpose, tenant, jurisdiction, incident hold, user request, expiry, and derived-data cleanup. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for retention and deletion.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating retention and deletion as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for retention and deletion.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 07 laboratory and review

Practical laboratory

Design a telemetry policy for regulated data and test redaction, tenant isolation, deletion, and incident preservation.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore confidential observability and zero-knowledge compliance proofs.

Review gate

Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 08

Operations, replay, and assurance

Use telemetry to diagnose, reproduce, and govern system behavior.

Chapter operating position
Use telemetry to diagnose, reproduce, and govern system behavior.

8.1 Dashboards and SLOs

Dashboards and SLOs must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Monitor availability, task success, latency, tokens, cost, tool errors, safety, and user outcomes. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for dashboards and slos.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating dashboards and slos as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for dashboards and slos.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.2 Trajectory replay

Trajectory replay must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Reconstruct model, context, tool, state, and environment with explicit nondeterminism and version limits. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for trajectory replay.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
agent_span:
  trace_id: mission-042
  span: verifier-7
  links: [implementer-3, test-suite-12]
  attributes:
    agent.role: verifier
    model.route: local-verifier
    task.state: running
    context.version: ctx-91
    tool.calls: 4
    gen_ai.usage.input_tokens: 18420
    gen_ai.usage.output_tokens: 2200
  evidence:
    - artifact: hidden-test-report
    - claim: candidate-safe-to-canary
```

Failure patterns

- Treating trajectory replay as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for trajectory replay.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.3 Incident response

Incident response must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Query affected missions, models, tools, sources, users, tenants, effects, and artifacts for containment. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for incident response.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating incident response as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for incident response.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

8.4 Assurance and audit

Assurance and audit must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Produce evidence bundles for release, control validation, exceptions, disputes, and external review. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the mission, task, harness, model call, context, retrieval, memory, tool effect, evaluation, and user outcome chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for assurance and audit.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating assurance and audit as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for assurance and audit.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 08 laboratory and review

Practical laboratory
Replay a failed agent mission using retained versions and identify which observations cannot be reproduced.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Develop an evidence operating system that treats every agentic outcome as a verifiable claim graph.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

Integrated learning roadmap

The guide is intended to be revisited. First establish fluency, then build a small implementation, operate it under failure, automate repeatable work, and finally evaluate emerging techniques against a stable baseline. Progress is demonstrated through evidence rather than reading completion alone.

Stage	Demonstrated capability
Foundation	Explain the system from first principles and trace its critical path without relying on product terminology.
Build	Implement the smallest representative system with explicit contracts, identities, telemetry, and tests.
Operate	Diagnose injected failures, recover safely, and preserve evidence of the causal chain.
Automate	Convert a proven manual workflow into bounded, idempotent, observable automation.
Architect	Design for scale, resilience, security, interoperability, and lifecycle change.
Explore	Evaluate frontier techniques using stated hypotheses, limitations, and adoption gates.

Source authority register

Source policy
Official standards, specifications, and project documentation remain with their issuing organizations. Mythos Systems provides original engineering interpretation, synthesis, implementation guidance, and relationship mapping. Source verification dates do not guarantee that an authority has not changed since review.

01. OpenTelemetry - OpenTelemetry
Role: Vendor-neutral telemetry APIs, SDKs, collectors, traces, metrics, and logs.
Verified: 2026-07-26
Official source: https://opentelemetry.io/

02. OpenTelemetry - OpenTelemetry Semantic Conventions 1.43.0
Role: Current semantic-convention baseline for interoperable telemetry.
Verified: 2026-07-26
Official source: https://opentelemetry.io/docs/specs/semconv/

03. OpenTelemetry - Generative AI Observability with OpenTelemetry
Role: Current GenAI observability guidance for model calls, tokens, content controls, tool calls, and results.
Verified: 2026-07-26
Official source: https://opentelemetry.io/blog/2026/genai-observability/

04. NIST - Artificial Intelligence Risk Management Framework 1.0
Role: Govern, Map, Measure, and Manage framework for trustworthy AI risk.
Verified: 2026-07-26
Official source: https://nvlpubs.nist.gov/nistpubs/ai/nist.ai.100-1.pdf

05. NIST - NIST AI 600-1 - Generative Artificial Intelligence Profile
Role: Generative-AI risk profile and recommended actions.
Verified: 2026-07-26
Official source: https://nvlpubs.nist.gov/nistpubs/ai/NIST.AI.600-1.pdf

06. Model Context Protocol - Model Context Protocol Specification 2025-11-25
Role: Stable protocol baseline for tool, resource, prompt, transport, authorization, lifecycle, and capability integration.
Verified: 2026-07-26
Official source: https://modelcontextprotocol.io/specification/2025-11-25

07. Agent2Agent Protocol - Agent2Agent Protocol Specification 1.0
Role: Open protocol for agent discovery, communication, task delegation, status, artifacts, and interoperability.
Verified: 2026-07-26
Official source: https://a2a-protocol.org/v1.0.0/

Authority application and refresh triggers

Authority class	Required library action
Protocols and specifications	Recheck interoperability, security considerations, defaults, and migration guidance when a referenced specification changes.
Security and assurance frameworks	Update control mappings, evidence expectations, risk language, and assessment procedures after material framework revision.
Languages, runtimes, and projects	Re-run examples, tests, deprecation checks, and operational recommendations against supported releases.
Benchmarks and evaluations	Re-execute claims when workloads, methods, models, compilers, drivers, hardware, or scoring rules change.
Operational evidence	Incorporate validated incidents, failure tests, reader corrections, and measured implementation outcomes into the next revision.

Limitations, freshness, and revision control

Boundary	Statement
Publication limitation	This guide synthesizes broad engineering practice. It does not replace product documentation, legal advice, safety certification, or environment-specific design review.
Evidence limitation	Not every pattern is benchmarked in every environment. Examples illustrate engineering methods and must be validated against actual versions, workloads, hardware, policy, and failure conditions.
Freshness limitation	Vendor behavior, software libraries, AI models, security threats, and emerging standards can change quickly. Volatile claims require source revalidation before operational adoption.
Adoption limitation	Frontier content is not an implicit adoption recommendation. Adoption requires defined value, qualification gates, controlled proof, rollback, ownership, and residual-risk acceptance.
Status boundary	Candidate Focused Field Guide describes the publication, not certification of a product, implementation, engineer, or organization.

Revision record

Version	Revision statement
1.0.0-candidate	Initial candidate living-guide edition. Published 2026-07-26; scheduled review 2026-10-26.

Search and relationship metadata

Dimension	Engineering position

Publication position
This is a living field guide. It is designed for frequent revision while retaining a stable permanent identity. Candidate status means the content is ready for structured use and review but is not represented as an external certification or authority publication.

LEVEL	CLASS	CADENCE	EVIDENCE
L1-L4	FIELD GUIDE	QUARTERLY	SOURCE-BOUND
Foundational through frontier	Practical and educational	Interim updates as needed	Limitations remain visible

Reader orientation

Dimension	Engineering position
Primary domain	MYTHOS-AI - Artificial Intelligence & Agentic Systems
Secondary domain	MYTHOS-SWE; MYTHOS-SEC; MYTHOS-DAT
Audience	Software-development leaders, agentic platform engineers, coding-agent architects, security teams, and advanced engineering organizations.
Prerequisites	Software engineering, AI-assisted development, agent runtimes, testing, CI/CD, security, and observability.
Publisher / owner	Mythos Systems / Aaron Stovall
Public classification	Public technical guidance

Expected outcomes

Design end-to-end autonomous workflows around specifications, repository authority, isolation, and acceptance evidence.

Use multiple agents, models, and harnesses for planning, implementation, testing, review, and operations.

Prevent generated code from bypassing architecture, security, quality, provenance, and deployment controls.

Maintain long-running development missions through checkpoints, retries, conflict resolution, and human intervention.

Evaluate autonomy by verified software outcomes, maintainability, incident rate, cost, and recovery.

How to use this guide

Read the guide as a progressive system rather than a disconnected encyclopedia. Foundational material establishes the mental model; practitioner sections convert it into repeatable implementation and operations; advanced sections expose architecture, scale, security, and failure behavior; frontier sections describe technologies whose evidence or maturity is still evolving.

Suggested reading path
New practitioners should follow the chapters in order and complete the laboratories. Experienced engineers may begin with the architecture, failure, validation, or frontier sections, then use the related-document map to deepen a specific topic.

Learning and assurance model

Level	Reader outcome
L1 - Foundational	Terminology, first principles, component roles, packet or state flow, and simple working examples.
L2 - Practitioner	Implementation, configuration, automation, testing, troubleshooting, and operational evidence.
L3 - Advanced	Architecture, scale, concurrency, resilience, threat models, performance, and complex migrations.
L4 - Frontier	Emerging systems, research directions, technical uncertainty, readiness gates, and adoption signals.

Contents

CHAPTER 01

Autonomy levels and development operating model

Define how much of the lifecycle the system may perform and who remains accountable.

Chapter operating position
Define how much of the lifecycle the system may perform and who remains accountable.

1.1 Assistance-to-autonomy spectrum

Assistance-to-autonomy spectrum must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Separate suggestion, patch, bounded task, multi-task mission, release candidate, and controlled operation. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for assistance-to-autonomy spectrum.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating assistance-to-autonomy spectrum as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for assistance-to-autonomy spectrum.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.2 Human authority and review

Human authority and review must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Assign product, architecture, security, code owner, release, operations, and incident decisions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for human authority and review.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
development_mission:
  objective: migrate authorization policy
  repository_revision: 8f2a...
  tracks:
    - architecture
    - implementation
    - migration
    - tests
    - security-review
    - operations
  gates:
    - compiler_and_schema_pass
    - backward_compatibility_pass
    - adversarial_tests_pass
    - migration_rollback_pass
    - canary_slo_pass
```

Failure patterns

Treating human authority and review as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for human authority and review.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.3 Mission contract

Mission contract must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Define objective, repository, scope, constraints, architecture, tools, budget, risk, and terminal evidence. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for mission contract.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating mission contract as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for mission contract.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

1.4 Safe stop and escalation

Safe stop and escalation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Pause on ambiguity, changing requirements, policy conflict, external effect, failed verification, or budget exhaustion. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for safe stop and escalation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating safe stop and escalation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for safe stop and escalation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 01 laboratory and review

Practical laboratory
Create autonomy policies for documentation, bug fixes, dependency updates, migrations, and production incidents.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore adaptive autonomy earned through domain-specific evidence.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 02

Repository intelligence and source of truth

Construct an accurate working model of a large codebase.

Chapter operating position
Construct an accurate working model of a large codebase.

2.1 Code and dependency graph

Code and dependency graph must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Index modules, symbols, calls, types, ownership, APIs, data, infrastructure, tests, and runtime paths. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for code and dependency graph.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating code and dependency graph as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for code and dependency graph.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.2 Documentation and decision history

Documentation and decision history must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Retrieve architecture records, issues, incidents, standards, migrations, and accepted constraints. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for documentation and decision history.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
development_mission:
  objective: migrate authorization policy
  repository_revision: 8f2a...
  tracks:
    - architecture
    - implementation
    - migration
    - tests
    - security-review
    - operations
  gates:
    - compiler_and_schema_pass
    - backward_compatibility_pass
    - adversarial_tests_pass
    - migration_rollback_pass
    - canary_slo_pass
```

Failure patterns

Treating documentation and decision history as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for documentation and decision history.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.3 Change impact and blast radius

Change impact and blast radius must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Identify callers, consumers, schemas, data, deployments, tests, security, and operations. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for change impact and blast radius.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating change impact and blast radius as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for change impact and blast radius.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

2.4 Freshness and invalidation

Freshness and invalidation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Track commits, branches, generated files, build outputs, schema versions, and concurrent changes. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for freshness and invalidation.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating freshness and invalidation as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for freshness and invalidation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 02 laboratory and review

Practical laboratory
Build a repository map for a cross-service schema change and compare it with actual compiler and test impact.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore live semantic twins synchronized with builds and runtime traces.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 03

Planning, architecture, and task graph generation

Convert intent into a dependency-aware, reviewable execution plan.

Chapter operating position
Convert intent into a dependency-aware, reviewable execution plan.

3.1 Requirement and acceptance derivation

Requirement and acceptance derivation must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Extract behavior, nonfunctional needs, compatibility, migration, observability, and proof. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for requirement and acceptance derivation.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating requirement and acceptance derivation as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for requirement and acceptance derivation.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.2 Architecture alternatives

Architecture alternatives must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Generate options, tradeoffs, risks, decisions, interfaces, state, and failure behavior. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for architecture alternatives.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
development_mission:
  objective: migrate authorization policy
  repository_revision: 8f2a...
  tracks:
    - architecture
    - implementation
    - migration
    - tests
    - security-review
    - operations
  gates:
    - compiler_and_schema_pass
    - backward_compatibility_pass
    - adversarial_tests_pass
    - migration_rollback_pass
    - canary_slo_pass
```

Failure patterns

Treating architecture alternatives as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for architecture alternatives.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.3 Task graph and ownership

Task graph and ownership must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Decompose research, code, data, tests, docs, security, deployment, and validation. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for task graph and ownership.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating task graph and ownership as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for task graph and ownership.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

3.4 Plan verification

Plan verification must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Check dependencies, scope, feasibility, contradictions, unowned work, rollback, and critical path. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for plan verification.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating plan verification as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for plan verification.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 03 laboratory and review

Practical laboratory
Generate three architecture plans and have independent agents falsify assumptions before selecting one.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore formally constrained planner models using executable architecture specifications.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 04

Multi-harness implementation and integration

Execute work in parallel while preserving repository consistency.

Chapter operating position
Execute work in parallel while preserving repository consistency.

4.1 Isolated implementation branches

Isolated implementation branches must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Assign worktrees, files, modules, tests, tools, model, context, and resource limits. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for isolated implementation branches.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating isolated implementation branches as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for isolated implementation branches.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.2 Generated code and transformations

Generated code and transformations must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use patches, ASTs, migrations, scaffolds, generators, and codemods with reviewable diffs. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for generated code and transformations.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
development_mission:
  objective: migrate authorization policy
  repository_revision: 8f2a...
  tracks:
    - architecture
    - implementation
    - migration
    - tests
    - security-review
    - operations
  gates:
    - compiler_and_schema_pass
    - backward_compatibility_pass
    - adversarial_tests_pass
    - migration_rollback_pass
    - canary_slo_pass
```

Failure patterns

Treating generated code and transformations as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for generated code and transformations.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.3 Continuous integration fan-in

Continuous integration fan-in must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Merge through contracts, compilers, tests, schemas, migrations, ownership, and conflict resolution. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for continuous integration fan-in.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating continuous integration fan-in as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for continuous integration fan-in.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

4.4 Provenance and attribution

Provenance and attribution must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Record mission, agent, model, prompts or task record, tools, artifacts, reviews, and decisions. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for provenance and attribution.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating provenance and attribution as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for provenance and attribution.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 04 laboratory and review

Practical laboratory
Run parallel implementation, test, and documentation harnesses and reconcile their work through a guarded integration branch.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore transactional repositories and semantic merge proofs.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 05

Autonomous testing, debugging, and repair

Generate evidence and causal fixes rather than repeated speculative edits.

Chapter operating position
Generate evidence and causal fixes rather than repeated speculative edits.

5.1 Test synthesis

Test synthesis must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Create unit, property, fuzz, contract, integration, concurrency, security, performance, and migration tests. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for test synthesis.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating test synthesis as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for test synthesis.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.2 Failure reproduction

Failure reproduction must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Preserve environment, inputs, versions, randomness, logs, traces, dumps, and minimal reproducer. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for failure reproduction.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
development_mission:
  objective: migrate authorization policy
  repository_revision: 8f2a...
  tracks:
    - architecture
    - implementation
    - migration
    - tests
    - security-review
    - operations
  gates:
    - compiler_and_schema_pass
    - backward_compatibility_pass
    - adversarial_tests_pass
    - migration_rollback_pass
    - canary_slo_pass
```

Failure patterns

Treating failure reproduction as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for failure reproduction.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.3 Causal debugging

Causal debugging must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Generate competing hypotheses, select discriminating experiments, update confidence, and stop low-value search. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for causal debugging.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating causal debugging as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for causal debugging.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

5.4 Repair and regression

Repair and regression must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Apply minimal change, validate root cause, prevent recurrence, and retain failed attempts. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for repair and regression.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.

Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.

Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.

Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

Treating repair and regression as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for repair and regression.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

Chapter 05 laboratory and review

Practical laboratory
Give agents a nondeterministic distributed failure and require a reproducible test, causal diagnosis, fix, and regression suite.

Laboratory evidence package

- Architecture or topology showing boundaries, identities, dependencies, and authoritative inputs.
- Versioned configuration or code with explanatory comments and reproducible setup instructions.
- Nominal-path validation plus at least two injected failure or boundary conditions.
- Structured logs, traces, metrics, packet captures, test output, or other appropriate evidence.
- A concise decision record covering findings, limitations, residual risks, and next actions.

Frontier extension

Explore execution-trace-guided repair and verifier-driven program synthesis.

Review gate
Advance only when another engineer can reproduce the result, explain the architecture, identify the failure boundary, and distinguish measured evidence from assumptions or projections.

CHAPTER 06

Review, adversarial assurance, and verified completion

Require independent evidence before accepting autonomous work.

Chapter operating position
Require independent evidence before accepting autonomous work.

6.1 Independent code and architecture review

Independent code and architecture review must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Use separate agents or humans for correctness, security, reliability, performance, and maintainability. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for independent code and architecture review.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Failure patterns

- Treating independent code and architecture review as a feature rather than an end-to-end stateful system.
- Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.
- Trusting controller, agent, or proxy status without validating external state and user outcome.
- Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.
- Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.
- Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for independent code and architecture review.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.2 Adversarial review

Adversarial review must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Search for prompt injection, malicious repository content, hidden side effects, test gaming, and policy bypass. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

- Define authority, ownership, desired state, dependencies, limits, and evidence for adversarial review.
- Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.
- Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
- Test nominal, prohibited, overloaded, partitioned, partially failed, recovery, upgrade, and rollback cases.
- Preserve configuration, policy, model, source, trace, event, artifact, approval, and user-outcome evidence.
- Scale through quotas, queues, backpressure, fairness, isolation, canaries, and deterministic fan-in.

Implementation sketch

```
development_mission:
  objective: migrate authorization policy
  repository_revision: 8f2a...
  tracks:
    - architecture
    - implementation
    - migration
    - tests
    - security-review
    - operations
  gates:
    - compiler_and_schema_pass
    - backward_compatibility_pass
    - adversarial_tests_pass
    - migration_rollback_pass
    - canary_slo_pass
```

Failure patterns

Treating adversarial review as a feature rather than an end-to-end stateful system.

Scaling worker count or deployment scope before bounding queues, budgets, retries, and fan-in.

Trusting controller, agent, or proxy status without validating external state and user outcome.

Sharing credentials, workspaces, caches, or context across tenants and roles without explicit policy.

Allowing AI-generated plans, policies, or changes to bypass deterministic validation and human authority.

Declaring recovery after process restart without reconciling orphan effects, leases, artifacts, and evidence.

Validation and evidence

Method	Expected evidence
Examine	Requirements, APIs, identities, state machines, policies, versions, resources, and dependencies for adversarial review.
Observe	Queue, task, controller, model, tool, route, proxy, event, resource, trace, artifact, and user-visible state.
Test	Expected, prohibited, malformed, duplicate, overloaded, partitioned, failed, recovery, upgrade, and rollback conditions.
Measure	Task success, reliability, latency, throughput, fairness, cost, token and compute use, blast radius, and operator burden.
Reconcile	Desired and planned state against actual cloud, cluster, agent, network, data, external-effect, and evidence state.

6.3 Acceptance evidence

Acceptance evidence must be engineered as a governed distributed-system mechanism, not a product label, agent persona, YAML object, or diagram. Require every criterion, test, static check, benchmark, migration, documentation, observability, and rollback. The design should identify authoritative state, workload identities, typed contracts, resource and token budgets, trust boundaries, failure domains, telemetry, rollback, and acceptance evidence.

This guide traces the subject through the request, specification, repository graph, plan, isolated work, test, review, release, operation, and maintenance chain. A running agent, reconciled object, successful API call, healthy proxy, or completed function is not proof of the intended outcome. Desired state must be compared with applied state, external effects, negative tests, degraded behavior, causal evidence, cost, and user or mission results.

Production engineering begins with a minimal known-good control plane and explicit invariants. Add one worker class, model route, controller, policy, event source, gateway, or platform feature at a time; preserve before-state evidence; test authorized and prohibited behavior; inject realistic failures; and retain a tested compensation or rollback path.

Troubleshooting locates the first divergence from the expected state machine. Account for stale watches, leases, retries, eventual consistency, duplicated work, cache state, identity rotation, partial external effects, version skew, prompt injection, overload, network partitions, and missing telemetry. Closure requires causal explanation, reproducibility, validated recovery, and residual limitations.

Engineering practices

Define authority, ownership, desired state, dependencies, limits, and evidence for acceptance evidence.

Use typed APIs, stable identities, explicit state machines, idempotency, and bounded effects.

Separate control plane, execution plane, data plane, evidence plane, and human decision authority.
